Adaptive Harvest Management

2018 Hunting Season

Adaptive Harvest Management

2018 Hunting Season

PREFACE

The process of setting waterfowl hunting regulations is conducted annually in the United States (U.S.; Blohm 1989) and involves a number of meetings where the status of waterfowl is reviewed by the agencies responsible for setting hunting regulations. In addition, the U.S. Fish and Wildlife Service (USFWS) publishes proposed regulations in the Federal Register to allow public comment. This document is part of a series of reports intended to support development of harvest regulations for the 2018 hunting season. Specifically, this report is intended to provide waterfowl managers and the public with information about the use of adaptive harvest management (AHM) for setting waterfowl hunting regulations in the U.S. This report provides the most current data, analyses, and decision-making protocols. However, adaptive management is a dynamic process and some information presented in this report will differ from that in previous reports.

1 EXECUTIVE SUMMARY

In 1995 the U.S. Fish and Wildlife Service (USFWS) implemented the adaptive harvest management (AHM) program for setting duck hunting regulations in the United States (U.S.). The AHM approach provides a framework for making objective decisions in the face of incomplete knowledge concerning waterfowl population dynamics and regulatory impacts.

The 2018 regulatory process implements the recommendations specified in the Final Supplemental Environmental Impact Statement on the Issuance of Annual Regulations Permitting the Hunting of Migratory Birds (SEIS 2013). As a result, revised AHM protocols include a shift in decision timing where the regulations for the 2018 hunting season will be determined in the fall of 2017. Adjustments to AHM decision frameworks have been developed to inform duck hunting regulations based on the breeding populations and habitat conditions observed in 2017 and the regulatory alternatives selected for the 2017 hunting season.

The AHM protocol is based on the population dynamics and status of three mallard (*Anas platyrhynchos*) stocks. Mid-continent mallards are defined as those breeding in the Waterfowl Breeding Population and Habitat Survey (WBPHS) strata 13–18, 20–50, and 75–77 plus mallards breeding in the states of Michigan, Minnesota, and Wisconsin (state surveys). The prescribed regulatory alternative for the Mississippi and Central Flyways depends exclusively on the status of these mallards. In 2017, the Atlantic Flyway and the USFWS agreed to remove stratum 54 from the eastern mallard stock because of safety concerns associated with aerial survey operations in this area. Therefore, eastern mallards are now defined as those breeding in WBPHS strata 51–53 and 56 and in the states of Virginia northward into New Hampshire (Atlantic Flyway Breeding Waterfowl Survey [AFBWS]). The regulatory choice for the Atlantic Flyway depends exclusively on the status of these mallards. Western mallards are defined as those breeding in WBPHS strata 1–12 (hereafter Alaska) and in the states of California, Oregon, Washington, and the Canadian province of British Columbia (hereafter southern Pacific Flyway). The prescribed regulatory alternative for the Pacific Flyway depends exclusively on the status of these mallards.

Mallard population models are based on the best available information and account for uncertainty in population dynamics and the impact of harvest. Model-specific weights reflect the relative confidence in alternative hypotheses and are updated annually using comparisons of predicted to observed population sizes. For mid-continent mallards, current model weights favor the weakly density-dependent reproductive hypothesis (>99%) and the additive-mortality hypothesis (71%). For eastern mallards, current model weights favor the weakly density-dependent reproductive hypothesis (94%) and the additive-mortality hypothesis (80%). Unlike mid-continent and eastern mallards, we consider a single functional form to predict western mallard population dynamics but consider a wide range of parameter values each weighted relative to the support from the data.

For the 2018 hunting season, the USFWS is considering the same regulatory alternatives as last year. The nature of the restrictive, moderate, and liberal alternatives has remained essentially unchanged since 1997, except that extended framework dates have been offered in the moderate and liberal alternatives since 2002. Harvest rates associated with each of the regulatory alternatives have been updated based on preseason band-recovery data. The expected harvest rates of adult males under liberal hunting seasons are 0.11 (SD = 0.02), 0.14 (SD = 0.03), and 0.13 (SD = 0.03) for mid-continent, eastern, and western mallards, respectively.

Optimal regulatory strategies for the 2018 hunting season were calculated using: (1) harvest-management objectives specific to each mallard stock; (2) current regulatory alternatives; and (3) current population models and their relative weights. Based on liberal regulatory alternatives selected for the 2017 hunting season, the 2017 survey results of 10.64 million mid-continent mallards, 4.33 million ponds in Prairie Canada, 0.65 million eastern mallards, and 0.98 million western mallards observed in Alaska (0.54 million) and the southern Pacific Flyway (0.44 million), the optimal choice for the 2018 hunting season in all four Flyways is the liberal regulatory alternative.

AHM concepts and tools have been successfully applied toward the development of formal adaptive harvest management protocols that inform American black duck (*Anas rubripes*), northern pintail (*Anas acuta*), and scaup (*Aythya affinis, A. marila*) harvest decisions.

For black ducks, the optimal country-specific regulatory strategies for the 2018 hunting season were calculated using: (1) an objective to achieve 98% of the maximum, long-term cumulative harvest; (2) current country-specific black duck regulatory alternatives; and (3) updated model parameters and weights. Based on a liberal regulatory alternative selected by Canada and a moderate regulatory alternative selected by the United States for the 2017 hunting season and the 2017 survey results of 0.54 million breeding black ducks and 0.44 million breeding mallards observed in the core survey area, the optimal regulatory choices for the 2018 hunting season are the liberal regulatory alternative in Canada and the moderate regulatory alternative in the United States.

For pintails, the optimal regulatory strategy for the 2018 hunting season was calculated using: (1) an objective of maximizing long-term cumulative harvest; (2) current pintail regulatory alternatives; and (3) current population models and their relative weights. Based on a liberal regulatory alternative with a 1-bird daily bag limit selected for the 2017 hunting season and the 2017 survey results of 2.89 million pintails observed at a mean latitude of 56.7 degrees, the optimal regulatory choice for the 2018 hunting season for all four Flyways is the liberal regulatory alternative with a 2-bird daily bag limit.

For scaup, the optimal regulatory strategy for the 2018 hunting season was calculated using: (1) an objective to achieve 95% of the maximum, long-term cumulative harvest; (2) current scaup regulatory alternatives; and (3) updated model parameters and weights. Based on a moderate regulatory alternative selected for the 2017 hunting season and the 2017 survey results of 4.37 million scaup, the optimal regulatory choice for the 2018 hunting season for all four Flyways is the moderate regulatory alternative.

2 BACKGROUND

The annual process of setting duck-hunting regulations in the U.S. is based on a system of resource monitoring, data analyses, and rule-making (Blohm 1989). Each year, monitoring activities such as aerial surveys, preseason banding, and hunter questionnaires provide information on population size, habitat conditions, and harvest levels. Data collected from this monitoring program are analyzed each year, and proposals for duck-hunting regulations are developed by the Flyway Councils, States, and USFWS. After extensive public review, the USFWS announces regulatory guidelines within which States can set their hunting seasons.

In 1995, the USFWS adopted the concept of adaptive resource management (Walters 1986) for regulating duck harvests in the U.S. This approach explicitly recognizes that the consequences of hunting regulations cannot be predicted with certainty and provides a framework for making objective decisions in the face of that uncertainty (Williams and Johnson 1995). Inherent in the adaptive approach is an awareness that management performance can be maximized only if regulatory effects can be predicted reliably. Thus, adaptive management relies on an iterative cycle of monitoring, assessment, and decision-making to clarify the relationships among hunting regulations, harvests, and waterfowl abundance (Johnson et al. 2016).

In regulating waterfowl harvests, managers face four fundamental sources of uncertainty (Nichols et al. 1995a, Johnson et al. 1996, Williams et al. 1996):

(1) environmental variation – the temporal and spatial variation in weather conditions and other key features of waterfowl habitat; an example is the annual change in the number of ponds in the Prairie Pothole Region, where water conditions influence duck reproductive success;

(2) partial controllability – the ability of managers to control harvest only within limits; the harvest resulting from a particular set of hunting regulations cannot be predicted with certainty because of variation in weather conditions, timing of migration, hunter effort, and other factors;

(3) partial observability – the ability to estimate key population attributes (e.g., population size, reproductive rate, harvest) only within the precision afforded by extant monitoring programs; and

(4) structural uncertainty – an incomplete understanding of biological processes; a familiar example is the long-standing debate about whether harvest is additive to other sources of mortality or whether populations compensate for hunting losses through reduced natural mortality. Structural uncertainty increases contentiousness in the decision-making process and decreases the extent to which managers can meet long-term conservation goals.

AHM was developed as a systematic process for dealing objectively with these uncertainties. The key components of AHM include (Johnson et al. 1993, Williams and Johnson 1995):

(1) a limited number of regulatory alternatives, which describe Flyway-specific season lengths, bag limits, and framework dates;

(2) a set of population models describing various hypotheses about the effects of harvest and environmental factors on waterfowl abundance;

(3) a measure of reliability (probability or "weight") for each population model; and

(4) a mathematical description of the objective(s) of harvest management (i.e., an "objective function"), by which alternative regulatory strategies can be compared.

These components are used in a stochastic optimization procedure to derive a regulatory strategy. A regulatory strategy specifies the optimal regulatory choice, with respect to the stated management objectives, for each possible combination of breeding population size, environmental conditions, and model weights (Johnson et al. 1997). The setting of annual hunting regulations then involves an iterative process:

(1) each year, an optimal regulatory choice is identified based on resource and environmental conditions, and on current model weights;

(2) after the regulatory decision is made, model-specific predictions for subsequent breeding population size are determined;

(3) when monitoring data become available, model weights are increased to the extent that observations of population size agree with predictions, and decreased to the extent that they disagree; and

(4) the new model weights are used to start another iteration of the process.

By iteratively updating model weights and optimizing regulatory choices, the process should eventually identify which model is the best overall predictor of changes in population abundance. The process is optimal in the sense that it provides the regulatory choice each year necessary to maximize management performance. It is adaptive in the sense that the harvest strategy evolves to account for new knowledge generated by a comparison of predicted and observed population sizes.

3   ADJUSTMENTS FOR SEIS 2013

The SEIS 2013 proposed several recommendations to adjust the annual decision-making process for establishing migratory bird hunting regulations (U.S. Department of the Interior 2013). Under the preferred alternative, a modified annual meeting schedule was recommended to streamline the regulatory process (Appendix B) and included the following considerations:

- early and late season regulatory actions are combined into a single process;

- regulatory proposals are developed based on data from the previous year, model predictions, or current-year information;

- the status of waterfowl would be made available to the public in August;

- Flyway and Council meetings would be held in the early Fall with proposals for the next year's hunting season considered by the Service Regulations Committee (SRC) in late October;

- SRC recommendations for the next year's hunting season would be forwarded to the Service Director and Assistant Secretary with proposed frameworks published in the Federal Register in December;

- the Final rule would then be published in late February and States would make selections by late April.

The primary consequence of the new decision process is the scheduling of a single regulatory meeting in the fall of year t to inform regulations for the next year's hunting season in year $t + 1$. As a result, regulatory decisions are made in advance of observing the status of waterfowl breeding populations (BPOP) and habitat conditions during the spring prior to the upcoming hunting season (Table 1). With the implementation of the SEIS, pre-survey regulatory decisions introduce a lag in the AHM process where model weight updating and state-dependent decision making are now governed by the previous year's monitoring information. Given that the original AHM protocols and decision frameworks were structured to inform decisions based on current monitoring information (i.e., post-survey), several technical adjustments and a new optimization framework were developed to support a pre-survey decision process. We revised the optimization procedures used to derive harvest policies by structuring the decision process based on the information that is available at the time of the decision, which includes the previous year's observation of the system, the previous year's regulation, and the latest update of model weights (Figure 1). Based on this new formulation, the prediction of future system states and harvest values must now account for all possible outcomes from previous decisions, and as a result, the optimal policy is now conditional on the previous year's regulation. We modified the optimization code used for each AHM decision framework in order to continue to use stochastic dynamic programming

Table 1 – Decision timing and key events that define the annual regulatory process under the original adaptive harvest management protocol (post-survey) compared to the new decision-making process specified in the SEIS 2013 (pre-survey). Under the pre-survey protocol, decisions for the hunting season in year $t + 1$ are made in October of year t based on observations of BPOP and ponds and the regulation selected for year t.

Month	Post-survey adaptive harvest management	Pre-survey adaptive harvest management (SEIS 2013)
Oct(t-1)		Inform regulatory decision for year t based on observations and regulations from year t-1
May(t)	Observe BPOP, ponds, and harvest rates	Observe BPOP, ponds, and harvest rates
July(t)	Update model weights and harvest rate distributions	Update model weights and harvest rate distributions
	Derive policy for hunting season in year t	
Aug(t)	Inform regulatory decision for year t based on observations from year t	Derive policy for hunting season in year $t+1$
Oct(t)		Inform regulatory decision for year $t+1$ based on observations and regulations from year t

(Williams et al. 2002) to derive optimal harvest policies while accounting for the pre-survey decision process (Johnson et al. 2016). Adjustments to these optimization procedures necessitated considerations of how closed season constraints and different objective functions were represented. Currently, we have implemented the closed season constraints and utility devaluation for mid-continent mallards conditional on the last observed state. With the coordination of the Harvest Management Working Group, we are exploring alternative ways to implement these constraints that would be more consistent with the intent of the original specification (i.e., post-survey decision framework). A comparison of optimization and simulation results from pre- and post-survey AHM protocols suggested that the adjustments to the optimization procedures to account for changes in decision timing were not expected to result in major changes in expected management performance (Boomer et al. 2015). Updated optimization code was developed with the MDPSOLVE© (Fackler 2011) software tools implemented in MATLAB (2016).

4   MALLARD STOCKS AND FLYWAY MANAGEMENT

Since its inception AHM has focused on the population dynamics and harvest potential of mallards, especially those breeding in mid-continent North America. Mallards constitute a large portion of the total U.S. duck harvest, and traditionally have been a reliable indicator of the status of many other species. Geographic differences in the reproduction, mortality, and migrations of mallard stocks suggest that there may be corresponding differences in optimal levels of sport harvest. The ability to regulate harvests of mallards originating from various breeding areas is complicated, however, by the fact that a large degree of mixing occurs during the hunting season. The challenge for managers, then, is to vary hunting regulations among Flyways in a manner that recognizes each Flyway's unique breeding-ground derivation of mallards. Of course, no Flyway receives mallards exclusively from one breeding area; therefore, Flyway-specific harvest strategies ideally should account for multiple breeding stocks that are exposed to a common harvest.

The optimization procedures used in AHM can account for breeding populations of mallards beyond the mid-continent region, and for the manner in which these ducks distribute themselves among the Flyways during the hunting season. An optimal approach would allow for Flyway-specific regulatory strategies, which represent an average of the optimal harvest strategies for each contributing breeding stock weighted by the relative size of each stock in the fall flight. This joint optimization of multiple mallard stocks requires: (1) models of population dynamics for all recognized stocks of mallards; (2) an objective function that accounts for harvest-management goals for all mallard stocks in the aggregate; and (3) decision rules allowing Flyway-specific regulatory choices. At present, however, a joint optimization of western, mid-continent, and eastern

stocks is not feasible due to computational hurdles. However, our preliminary analyses suggest that the lack of a joint optimization does not result in a significant decrease in performance.

Currently, three stocks of mallards are officially recognized for the purposes of AHM (Figure 2). We use a constrained approach to the optimization of these stocks' harvest, in which the Atlantic Flyway regulatory strategy is based exclusively on the status of eastern mallards, the regulatory strategy for the Mississippi and Central Flyways is based exclusively on the status of mid-continent mallards, and the Pacific Flyway regulatory strategy is based exclusively on the status of western mallards.

5 MALLARD POPULATION DYNAMICS

5.1 Mid-continent Stock

Mid-continent mallards are defined as those breeding in WBPHS strata 13–18, 20–50, and 75–77, and in the Great Lakes region (Michigan, Minnesota, and Wisconsin; see Figure 2). Estimates of this population have varied from 6.3 to 11.9 million since 1992 (Table D.1, Figure 3). Estimated breeding-population size in 2017 was 10.64 million (SE = 0.33 million), including 9.95 million (SE = 0.33 million) from the WBPHS and 0.69 million (SE = 0.05 million) from the Great Lakes region.
Figure 3 – Population estimates of mid-continent mallards observed in the WBPHS (strata: 13–18, 20–50, and 75–77) and the Great Lakes region (Michigan, Minnesota, and Wisconsin) from 1992 to 2017. Error bars represent one standard error.

Details describing the set of population models for mid-continent mallards are provided in Appendix D. The set consists of four alternatives, formed by the combination of two survival hypotheses (additive vs. compensatory hunting mortality) and two reproductive hypotheses (strongly vs. weakly density dependent). Relative weights for the alternative models of mid-continent mallards changed little until all models under-predicted the change in population size from 1998 to 1999, perhaps indicating there is a significant factor affecting population dynamics that is absent from all four models (Figure 4). Updated model weights suggest a preference for the additive-mortality models (71%) over those describing hunting mortality as compensatory (29%). For most of the time frame, model weights have strongly favored the weakly density-dependent reproductive models over the strongly density-dependent ones, with current model weights greater than 99% and less than 1%, respectively. The reader is cautioned, however, that models can sometimes make reliable predictions of population size for reasons having little to do with the biological hypotheses expressed therein (Johnson et al. 2002*b*).

5.2 Eastern Stock

In the spring of 2017, the USFWS and the Atlantic Flyway agreed to remove stratum 54 from the eastern mallard stock because of safety concerns that preclude the continued monitoring of this area's breeding waterfowl through fixed-wing aircraft survey operations. As a result, eastern mallards are defined as those breeding in southern Ontario and Quebec (WBPHS strata 51–53 and 56) and in the northeastern United States (AFBWS; Heusmann and Sauer 2000, see Figure 2). Estimates of this population have varied from 0.65 to 1.07 million since 1990, with the majority of the population accounted for in the northeastern U.S. (Table E.1, Figure 5). For 2017, the estimated breeding-population size of eastern mallards was 0.65 million (SE = 0.05 million), including 0.20 million (SE = 0.03 million) from the WBPHS and 0.45 million (SE = 0.04 million) from the northeastern U.S.

Details describing the population models used for eastern mallard AHM are provided in Appendix E. The set consists of four alternatives, formed by the combination of two reproductive hypotheses (strongly vs. weakly density dependent) and two survival hypotheses (additive vs. compensatory hunting mortality). Model weights for the eastern mallard model set were computed with a retrospective assessment of relative model
Figure 4 – Top panel: population estimates of mid-continent mallards observed in the WBPHS compared to mid-continent mallard model set predictions (weighted average based on 2017 model weight updates) from 1996 to 2017. Error bars represent 95% confidence intervals. Bottom panel: mid-continent mallard model weights (SaRw = additive mortality and weakly density-dependent reproduction, ScRw = compensatory mortality and weakly density-dependent reproduction, SaRs = additive mortality and strongly density-dependent reproduction, ScRs = compensatory mortality and strongly density-dependent reproduction). Model weights were assumed to be equal in 1995.

performance based on the most reliable harvest rate information available from 2002 through 2016. The 2017 model weight updates calculated with the eastern mallard model set suggest support for the weakly density-dependent reproductive hypothesis (94%) and the additive harvest mortality hypothesis (80%; Figure 6).

5.3 Western Stock

Western mallards consist of 2 substocks and are defined as those birds breeding in Alaska (WBPHS strata 1–12) and those birds breeding in the southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined; see Figure 2). Estimates of these subpopulations have varied from 0.28 to 0.84 million in Alaska since 1990 and 0.43 to 0.65 million in the southern Pacific Flyway since 2010 (Table F.1, Figure 7). For 2017, the estimated breeding-population size of western mallards was 0.98 million (SE = 0.06 million), including 0.54 million (SE = 0.05 million) from Alaska and 0.44 million (SE = 0.03 million) from the southern Pacific Flyway.

Details concerning the set of population models for western mallards are provided in Appendix F. To predict changes in abundance we relied on a discrete logistic model, which combines reproduction and natural mortality into a single parameter, r, the intrinsic rate of growth. This model assumes density-dependent growth, which is regulated by the ratio of population size, N, to the carrying capacity of the environment, K (i.e., equilibrium population size in the absence of harvest). In the traditional formulation of the logistic model, harvest mortality is completely additive and any compensation for hunting losses occurs as a result of density-dependent responses beginning in the subsequent breeding season. To increase the model's generality we included a scaling parameter for harvest that allows for the possibility of compensation prior to the breeding season. It is important to note, however, that this parameterization does not incorporate any hypothesized mechanism for harvest compensation and, therefore, must be interpreted cautiously. We modeled Alaska mallards independently of those in the southern Pacific Flyway because of differing population
Figure 5 – Population estimates of eastern mallards observed in the northeastern states (AFBWS) and in southern Ontario and Quebec (WBPHS strata 51–53 and 56) from 1990 to 2017. In 2013, population estimates were only available for the northeastern states (AFBWS). Error bars represent one standard error.
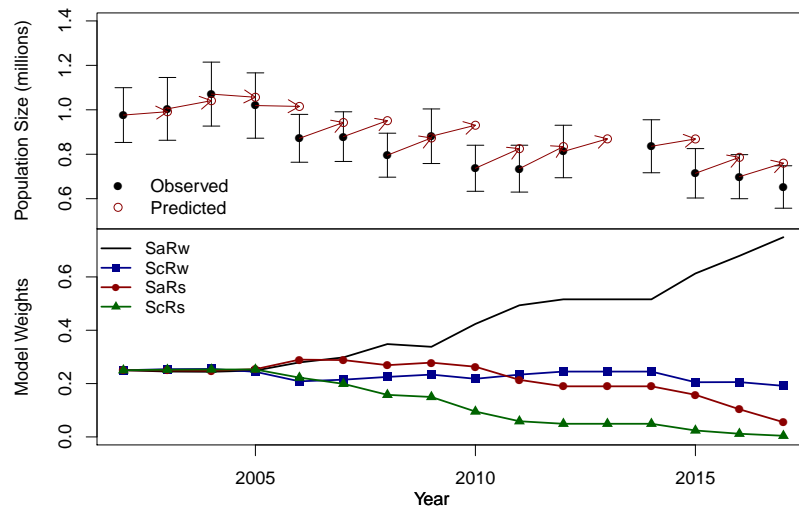

Figure 6 – Top panel: population estimates of eastern mallards observed in the WBPHS and the AFBWS compared to eastern mallard model set predictions (weighted average based on 2017 model weight updates) from 2003 to 2017. Error bars represent 95% confidence intervals. Bottom panel: eastern mallard model weights (SaRw = additive mortality and weakly density-dependent reproduction, ScRw = compensatory mortality and weakly density-dependent reproduction, SaRs = additive mortality and strongly density-dependent reproduction, ScRs = compensatory mortality and strongly density-dependent reproduction). Model weights were assumed to be equal in 2002; model weights were not updated in 2013–14.
Figure 7 – Population estimates of western mallards observed in Alaska (WBPHS strata 1–12) and the southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined) from 1990 to 2017. Error bars represent one standard error.

trajectories (see Figure 7) and substantial differences in the distribution of band recoveries.

We used Bayesian estimation methods in combination with a state-space model that accounts explicitly for both process and observation error in breeding population size (Meyer and Millar 1999). Breeding population estimates of mallards in Alaska are available since 1955, but we had to limit the time series to 1990–2017 because of changes in survey methodology and insufficient band-recovery data. The logistic model and associated posterior parameter estimates provided a reasonable fit to the observed time series of Alaska population estimates. The estimated median carrying capacity was 1.03 million and the intrinsic rate of growth was 0.31. The posterior median estimate of the scaling parameter was 1.35. Breeding population and harvest-rate data were available for California-Oregon mallards for the period 1992–2017. Because the British Columbia survey did not begin until 2006 and the Washington survey was redesigned in 2010, we imputed data in a Markov chain Monte Carlo (MCMC) framework from the beginning of the British Columbia and Washington surveys back to 1992 (see details in Appendix F) to make the time series consistent for the southern Pacific Flyway. The logistic model also provided a reasonable fit to these data. The estimated median carrying capacity was 0.87 million, and the intrinsic rate of growth was 0.23. The posterior median estimate of the scaling parameter was 0.59.

The AHM protocol for western mallards is structured similarly to that used for eastern mallards, in which an optimal harvest strategy is based on the status of a single breeding stock (Alaska and southern Pacific Flyway substocks) and harvest regulations in a single Flyway. Although the contribution of mid-continent mallards to the Pacific Flyway harvest is significant, we believe an independent harvest strategy for western mallards poses little risk to the mid-continent stock. Further analyses will be needed to confirm this conclusion, and to better understand the potential effect of mid-continent mallard status on sustainable hunting opportunities in the Pacific Flyway.

6 HARVEST-MANAGEMENT OBJECTIVES

The basic harvest-management objective for mid-continent mallards is to maximize cumulative harvest over the long term, which inherently requires perpetuation of a viable population. Moreover, this objective is constrained to avoid regulations that could be expected to result in a subsequent population size below the goal of the North American Waterfowl Management Plan (NAWMP). According to this constraint, the value of harvest decreases proportionally as the difference between the goal and expected population size increases. This balance of harvest and population objectives results in a regulatory strategy that is more conservative than that for maximizing long-term harvest, but more liberal than a strategy to attain the NAWMP goal (regardless of effects on hunting opportunity). The current objective for mid-continent mallards uses a population goal of 8.5 million birds, which consists of 7.9 million mallards from the WBPHS (strata 13–18, 20–50, and 75–77) corresponding to the mallard population goal in the 1998 update of the NAWMP (less the portion of the mallard goal comprised of birds breeding in Alaska) and a goal of 0.6 million for the combined states of Michigan, Minnesota, and Wisconsin.

For eastern and western mallards, there is no NAWMP goal or other established target for desired population size. Accordingly, the management objective for eastern and western mallards is to maximize long-term cumulative (i.e., sustainable) harvest.

7 REGULATORY ALTERNATIVES

7.1 Evolution of Alternatives

When AHM was first implemented in 1995, three regulatory alternatives characterized as liberal, moderate, and restrictive were defined based on regulations used during 1979–84, 1985–87, and 1988–93, respectively. These regulatory alternatives also were considered for the 1996 hunting season. In 1997, the regulatory alternatives were modified to include: (1) the addition of a very-restrictive alternative; (2) additional days and a higher duck bag limit in the moderate and liberal alternatives; and (3) an increase in the bag limit of hen mallards in the moderate and liberal alternatives. In 2002, the USFWS further modified the moderate and liberal alternatives to include extensions of approximately one week in both the opening and closing framework dates.

In 2003, the very-restrictive alternative was eliminated at the request of the Flyway Councils. Expected harvest rates under the very-restrictive alternative did not differ significantly from those under the restrictive alternative, and the very-restrictive alternative was expected to be prescribed for <5% of all hunting seasons. Also in 2003, at the request of the Flyway Councils the USFWS agreed to exclude closed duck-hunting seasons from the AHM protocol when the population size of mid-continent mallards (as defined in 2003: WBPHS strata 1–18, 20–50, and 75–77 plus the Great Lakes region) was ≥5.5 million. Based on our original assessment, closed hunting seasons did not appear to be necessary from the perspective of sustainable harvesting when the mid-continent mallard population exceeded this level. The impact of maintaining open seasons above this level also appeared negligible for other mid-continent duck species, as based on population models developed by Johnson (2003).

In 2008, the mid-continent mallard stock was redefined to exclude mallards breeding in Alaska, necessitating a re-scaling of the closed-season constraint. Initially, we attempted to adjust the original 5.5 million closure threshold by subtracting out the 1985 Alaska breeding population estimate, which was the year upon which the original closed season constraint was based. Our initial re-scaling resulted in a new threshold equal to 5.25 million. Simulations based on optimal policies using this revised closed season constraint suggested that the Mississippi and Central Flyways would experience a 70% increase in the frequency of closed seasons. At that time, we agreed to consider alternative re-scalings in order to minimize the effects on the mid-continent mallard strategy and account for the increase in mean breeding population sizes in Alaska over the past

several decades. Based on this assessment, we recommended a revised closed season constraint of 4.75 million which resulted in a strategy performance equivalent to the performance expected prior to the re-definition of the mid-continent mallard stock. Because the performance of the revised strategy is essentially unchanged from the original strategy, we believe it will have no greater impact on other duck stocks in the Mississippi and Central Flyways. However, complete- or partial-season closures for particular species or populations could still be deemed necessary in some situations regardless of the status of mid-continent mallards. Details of the regulatory alternatives for each Flyway are provided in Table 2.

7.2   Regulation-Specific Harvest Rates

Harvest rates of mallards associated with each of the open-season regulatory alternatives were initially predicted using harvest-rate estimates from 1979–84, which were adjusted to reflect current hunter numbers and contemporary specifications of season lengths and bag limits. In the case of closed seasons in the United States, we assumed rates of harvest would be similar to those observed in Canada during 1988–93, which was a period of restrictive regulations both in Canada and the United States. All harvest-rate predictions were based only in part on band-recovery data, and relied heavily on models of hunting effort and success derived from hunter surveys (Appendix C in U.S. Fish and Wildlife Service 2002). As such, these predictions had large sampling variances and their accuracy was uncertain.

In 2002, we began using Bayesian statistical methods for improving regulation-specific predictions of harvest rates, including predictions of the effects of framework-date extensions. Essentially, the idea is to use existing (prior) information to develop initial harvest-rate predictions (as above), to make regulatory decisions based on those predictions, and then to observe realized harvest rates. Those observed harvest rates, in turn, are

Table 2 – Regulatory alternatives for the 2018 duck-hunting season.

	Flyway			
Regulation	**Atlantic**[a]	**Mississippi**	**Central**[b]	**Pacific**[c]
Shooting Hours	one-half hour before sunrise to sunset			
	Framework Dates			
Restrictive	Oct 1–Jan 20	Saturday nearest Oct 1 to the Sunday nearest Jan 20		
Moderate	Saturday nearest September 24 to the last Sunday in January			
Liberal				
	Season Length (days)			
Restrictive	30	30	39	60
Moderate	45	45	60	86
Liberal	60	60	74	107
	Bag Limit (total / mallard / hen mallard)			
Restrictive	3 / 3 / 1	3 / 2 / 1	3 / 3 / 1	4 / 3 / 1
Moderate	6 / 4 / 2	6 / 4 / 1	6 / 5 / 1	7 / 5 / 2
Liberal	6 / 4 / 2	6 / 4 / 2	6 / 5 / 2	7 / 7 / 2

[a] The states of Maine, Massachusetts, Connecticut, Pennsylvania, New Jersey, Maryland, Delaware, West Virginia, Virginia, and North Carolina are permitted to exclude Sundays, which are closed to hunting, from their total allotment of season days.

[b] The High Plains Mallard Management Unit is allowed 12, 23, and 23 extra days in the restrictive, moderate, and liberal alternatives, respectively.

[c] The Columbia Basin Mallard Management Unit is allowed seven extra days in the restrictive and moderate alternatives.

treated as new sources of information for calculating updated (posterior) predictions. Bayesian methods are attractive because they provide a quantitative, formal, and an intuitive approach to adaptive management.

Annual harvest rate estimates for each mallard stock are updated with band-recovery information from a cooperative banding program between the USFWS and CWS, along with state, provincial, and other participating partners. Recovery rate estimates from these data are adjusted with reporting rate probabilities resulting from a recent reward band study from 2002 to 2010 (Boomer et al. 2013). For mid-continent mallards, we have empirical estimates of harvest rate from the recent period of liberal hunting regulations (1998–2016). Bayesian methods allow us to combine these estimates with our prior predictions to provide updated estimates of harvest rates expected under the liberal regulatory alternative. Moreover, in the absence of experience (so far) with the restrictive and moderate regulatory alternatives, we reasoned that our initial predictions of harvest rates associated with those alternatives should be re-scaled based on a comparison of predicted and observed harvest rates under the liberal regulatory alternative. In other words, if observed harvest rates under the liberal alternative were 10% less than predicted, then we might also expect that the mean harvest rate under the moderate alternative would be 10% less than predicted. The appropriate scaling factors currently are based exclusively on prior beliefs about differences in mean harvest rate among regulatory alternatives, but they will be updated once we have experience with something other than the liberal alternative. A detailed description of the analytical framework for modeling mallard harvest rates is provided in Appendix G.

Our models of regulation-specific harvest rates also allow for the marginal effect of framework-date extensions in the moderate and liberal alternatives. A previous analysis by the U.S. Fish and Wildlife Service (2001) suggested that implementation of framework-date extensions might be expected to increase the harvest rate of mid-continent mallards by about 15%, or in absolute terms by about 0.02 (SD = 0.01). Based on the observed harvest rates during the 2002–2016 hunting seasons, the updated (posterior) estimate of the marginal change in harvest rate attributable to the framework-date extension is 0.005 (SD = 0.006). The estimated effect of the framework-date extension has been to increase harvest rate of mid-continent mallards by about 5% over what would otherwise be expected in the liberal alternative. However, the reader is strongly cautioned that reliable inference about the marginal effect of framework-date extensions ultimately depends on a rigorous experimental design (including controls and random application of treatments).

Current predictions of harvest rates of adult-male mid-continent mallards associated with each of the regulatory alternatives are provided in Table 3. Predictions of harvest rates for the other age and sex cohorts are based on the historical ratios of cohort-specific harvest rates to adult-male rates (Runge et al. 2002). These ratios are considered fixed at their long-term averages and are 1.5407, 0.7191, and 1.1175 for young males, adult females, and young females, respectively. We make the simplifying assumption that the harvest rates of mid-continent mallards depend solely on the regulatory choice in the Mississippi and Central Flyways.

The predicted harvest rates of eastern mallards are updated in the same fashion as that for mid-continent mallards based on preseason banding conducted in eastern Canada and the northeastern United States (Appendix G). Like mid-continent mallards, harvest rates of age and sex cohorts other than adult male mallards are based on constant rates of differential vulnerability as derived from band-recovery data. For

Table 3 – Predictions of harvest rates of adult male, mid-continent, eastern, and western mallards expected with application of the 2018 regulatory alternatives in the Mississippi and Central, Atlantic, and Pacific Flyways.

Regulatory Alternative	Mid-continent		Eastern		Western	
	Mean	SD	Mean	SD	Mean	SD
Closed (U.S.)	0.009	0.002	0.080	0.023	0.009	0.018
Restrictive	0.055	0.013	0.103	0.039	0.068	0.017
Moderate	0.096	0.021	0.131	0.047	0.111	0.029
Liberal	0.113	0.017	0.139	0.035	0.134	0.028

eastern mallards, these constants are 1.1534, 1.3306, and 1.5090 for adult females, young males, and young females, respectively (Johnson et al. 2002a). Regulation-specific predictions of harvest rates of adult-male eastern mallards are provided in Table 3.

In contrast to mid-continent mallards, framework-date extensions were expected to increase the harvest rate of eastern mallards by only about 5% (U.S. Fish and Wildlife Service 2001), or in absolute terms by about 0.01 (SD = 0.01). Based on the observed harvest rates during the 2002–2016 hunting seasons, the updated (posterior) estimate of the marginal change in harvest rate attributable to the framework-date extension is 0.002 (SD = 0.009). The estimated effect of the framework-date extension has been to increase harvest rate of eastern mallards by about 1.13% over what would otherwise be expected in the liberal alternative.

Based on available estimates of harvest rates of mallards banded in California and Oregon during 1990–1995 and 2002–2007, there was no apparent relationship between harvest rate and regulatory changes in the Pacific Flyway. This is unusual given our ability to document such a relationship in other mallard stocks and in other species. We note, however, that the period 2002–2007 was comprised of both stable and liberal regulations and harvest rate estimates were based solely on reward bands. Regulations were relatively restrictive during most of the earlier period and harvest rates were estimated based on standard bands using reporting rates estimated from reward banding during 1987–1988. Additionally, 1993–1995 were transition years in which full-address and toll-free bands were being introduced and information to assess their reporting rates (and their effects on reporting rates of standard bands) is limited. Thus, the two periods in which we wish to compare harvest rates are characterized not only by changes in regulations, but also in estimation methods.

Consequently, we lack a sound empirical basis for predicting harvest rates of western mallards associated with current regulatory alternatives other than liberal in the Pacific Flyway. In 2009, we began using Bayesian statistical methods for improving regulation-specific predictions of harvest rates (see Appendix G). The methodology is analogous to that currently in use for mid-continent and eastern mallards except that the marginal effect of framework date extensions in moderate and liberal alternatives is inestimable because there are no data prior to implementation of extensions. In 2008, we specified prior regulation-specific harvest rates of 0.01, 0.06, 0.09, and 0.11 with associated standard deviations of 0.003, 0.02, 0.03, and 0.03 for the closed, restrictive, moderate, and liberal alternatives, respectively. The prior for the liberal regulation was then updated in 2011 with a harvest rate of 0.12 and standard deviation of 0.04. The harvest rates for the liberal alternative were based on empirical estimates realized under the current liberal alternative during 2002–2007 and determined from adult male mallards banded with reward and standard bands adjusted for band reporting rates in the southern Pacific Flyway. The development of priors was based on banding information from California and Oregon data only. Recently, we assessed the band-recovery data from Washington, Idaho, and British Columbia and found that the addition of these bands had a negligible influence on harvest rate estimates of western mallards. As a result, we have included Washington, Idaho, and British Columbia band-recovery information in our annual updates to western mallard harvest rate distributions. Harvest rates for the moderate and restrictive alternatives were based on the proportional (0.85 and 0.51) difference in harvest rates expected for mid-continent mallards under the respective alternatives. Finally, harvest rate for the closed alternative was based on what we might realize with a closed season in the United States (including Alaska) and a very restrictive season in Canada, similar to that for mid-continent mallards. A relatively large standard deviation (CV = 0.3) was chosen to reflect greater uncertainty about the means than that for mid-continent mallards (CV = 0.2). Current predictions of harvest rates of adult male western mallards associated with each regulatory alternative are provided in Table 3.

8   OPTIMAL REGULATORY STRATEGIES

Using stochastic dynamic programming (Williams et al. 2002) to evaluate a pre-survey decision process, we calculated the optimal regulatory strategy for the Mississippi and Central Flyways based on: (1) the dual objectives of maximizing long-term cumulative harvest and achieving a population goal of 8.5 million mid-continent mallards; (2) current regulatory alternatives and the closed-season constraint; and (3) current mid-continent mallard population models and associated weights. The resulting regulatory strategy includes
Figure 8 – Mid-continent mallard pre-survey harvest policies derived with updated optimization methods that account for changes in decision timing associated with adaptive harvest management protocols specified in the SEIS 2013. Harvest policies were calculated with current regulatory alternatives (including the closed-season constraint), mid-continent mallard models and weights, and the dual objectives of maximizing long-term cumulative harvest and achieving a population goal of 8.5 million mallards.

options conditional on the regulatory alternative selected the previous hunting season (Figure 8). Note that prescriptions for closed seasons in this strategy represent resource conditions that are insufficient to support one of the current regulatory alternatives, given current harvest-management objectives and constraints. However, closed seasons under all of these conditions are not necessarily required for long-term resource protection, and simply reflect the NAWMP population goal and the nature of the current regulatory alternatives. Assuming that harvest management adhered to this strategy (and that current model weights accurately reflect population dynamics), breeding-population size would be expected to average 7.03 million (SD = 1.53 million). Based on a liberal regulatory alternative selected for the 2017 hunting season, the estimated 2017 breeding population size of 10.64 million mid-continent mallards and 4.33 million ponds observed in Prairie Canada, the optimal choice for the 2018 hunting season in the Mississippi and Central Flyways is the liberal regulatory alternative (Table 4).

We calculated the optimal regulatory strategy for the Atlantic Flyway based on: (1) an objective to maximize long-term cumulative harvest; (2) current regulatory alternatives; and (3) current eastern mallard population models and associated weights. The resulting regulatory strategy includes options conditional on the regulatory alternative selected the previous hunting season (Table 5). We simulated the use of this regulatory strategy to determine expected performance characteristics. Assuming that harvest management adhered to this strategy (and that 2017 model weights accurately reflect population dynamics), breeding-population size would be expected to average 1.01 million (SD = 0.21 million). Based on a liberal regulatory alternative selected for the 2017 hunting season and an estimated 2017 breeding population size of 0.65 million eastern mallards, the optimal choice for 2018 hunting season in the Atlantic Flyway is the liberal regulatory alternative (see Table 5).

We calculated the optimal regulatory strategy for the Pacific Flyway based on: (1) an objective to maximize long-term cumulative harvest; (2) current regulatory alternatives; and (3) current population models and parameter estimates. The resulting regulatory strategy includes options conditional on the regulatory alternative selected the previous hunting season (Figure 9). We simulated the use of this regulatory strategy to

Table 4 – Optimal regulatory strategy[a] for the Mississippi and Central Flyways for the 2018 hunting season predicated on a liberal alternative selected the previous year (2017). This strategy is based on the current regulatory alternatives (including the closed-season constraint), mid-continent mallard models and weights, and the dual objectives of maximizing long-term cumulative harvest and achieving a population goal of 8.5 million mallards. The shaded cell indicates the regulatory prescription for the 2018 hunting season.

Figure 9 – Western mallard pre-survey harvest policies derived with updated optimization methods that account for changes in decision timing associated with adaptive harvest management protocols specified under the SEIS 2013. This strategy is based on current regulatory alternatives, updated (1990–2017) western mallard population models and parameter estimates, and an objective to maximize long-term cumulative harvest.

determine expected performance characteristics. Assuming that harvest management adhered to this strategy (and that current model parameters accurately reflect population dynamics), breeding-population size would be expected to average 0.58 million (SD = 0.07 million) in Alaska and 0.54 million (SD = 0.06 million) in the southern Pacific Flyway. Based on a liberal regulatory alternative selected for the 2017 hunting season, an estimated 2017 breeding population size of 0.54 million mallards observed in Alaska, and 0.44 million observed in the southern Pacific Flyway, the optimal choice for the 2018 hunting season in the Pacific Flyway is the liberal regulatory alternative (Table 6).

9   APPLICATION OF ADAPTIVE HARVEST MANAGEMENT CONCEPTS TO OTHER STOCKS

The USFWS is working to apply the principles and tools of AHM to improve decision-making for several other stocks of waterfowl. Below, we provide AHM updates for the 2018 hunting season that are currently informing American black duck, northern pintail, and scaup harvest management decisions.

9.1   American Black Duck

Federal, state, and provincial agencies in the United States and Canada agreed that an international harvest strategy for black ducks is needed because the resource is valued by both countries and both countries have the ability to influence the resource through harvest. The partners also agreed a harvest strategy should be developed with an AHM approach based on the integrated breeding-ground survey data (Zimmerman et al. 2012, U.S. Fish and Wildlife Service 2013). Finally, the strategy should also provide a formal approach to determining appropriate harvest levels and fair allocation of the harvest between countries (Conroy 2010).

Table 6 – Optimal regulatory strategy[a] for the Pacific Flyway for the 2018 hunting season predicated on a liberal alternative selected the previous year (2017). This strategy is based on current regulatory alternatives, updated (1990–2017) western mallard population models and parameter estimates, and an objective to maximize long-term cumulative harvest. The shaded cell indicates the regulatory prescription for 2018.

[c] Estimated number of mallards (in millions) observed in the southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined).
Figure 10 – Functional form of the harvest parity constraint designed to allocate allowable black duck harvest equitably between the United States and Canada; p is the proportion of harvest allocated to one country, and U is the utility of a specific combination of country-specific harvest options in achieving the objective of black duck adaptive harvest management.

The overall goals of the Black Duck International Harvest strategy include:

(1) maintain a black duck population that meets legal mandates and provides consumptive and non-consumptive use commensurate with habitat carrying capacity;

(2) maintain societal values associated with the hunting tradition; and

(3) maintain equitable access to the black duck resource in Canada and the United States.

The objectives of the harvest strategy are to achieve 98% of the maximum, long-term cumulative harvest and to share the allocated harvest equitably (i.e., parity) between countries. Historically, the realized allocation of harvest between Canada and the United States has ranged from 40% to 60% in either country. Recognizing the historical allocation and acknowledging incomplete control over harvest, parity is achieved through a constraint which discounts combinations of country-specific harvest rates that are expected to result in allocation of harvest that is >50% in one country. The constraint applies a mild penalty on country-specific harvest options that result in one country receiving >50% but <60% of the harvest allocation and a stronger discount on combinations resulting in one country receiving >60% of the harvest allocation (Figure 10). The goals and objectives of the black duck AHM framework were developed through a formal consultation process with representatives from the CWS, USFWS, Atlantic Flyway Council, and Mississippi Flyway Council.

Country-specific harvest opportunities were determined from a set of expected harvest rate distributions defined as regulatory packages. Canada has developed 4 regulatory packages (liberal, moderate, restrictive and closed; Figure 11) and the United States has developed 3 (moderate, restrictive, closed; see Figure 11). Expected harvest rates under each regulatory package are updated annually by incorporating harvest data from the most recent hunting season. Canada and the United States will determine, independently, appropriate regulations designed to achieve their prescribed harvest targets as identified under the regulatory packages. Regulations will vary independently between countries based on the status of the population and optimal strategy as determined through the AHM protocol.

The AHM model is based on spring breeding-ground abundance as estimated by the integrated Eastern Waterfowl Survey from the core survey area. The core survey area is comprised of WBPHS survey strata 51, 52, 63, 64, 66, 67, 68, 70, 71, and 72 (see Figure 2). The American black duck population measure is based on "indicated pairs," defined as 1 individual observed equals 1 indicated pair whereas a group of 2 is assumed to represent 1.5 indicated pairs. Fall age ratios are estimated using harvest age ratios derived from
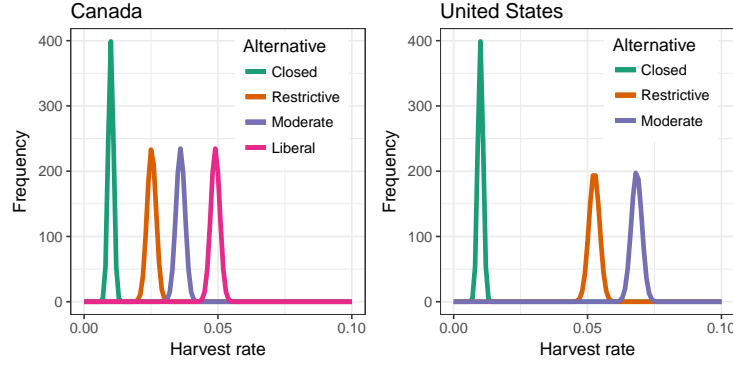

Figure 11 – Predictive harvest rate distributions for adult male black ducks expected under the application of the 2018 regulatory alternatives in Canada (left) and the United States (right).
Figure 12 – Updated estimates of mallard competition ($c2$; left panel), and black duck harvest additivity ($a1$; right panel) over time.

the USFWS and CWS parts collection surveys, adjusted for differential vulnerability. Age- and sex-specific harvest rates are based on direct recoveries of black ducks banded in eastern Canada, 1990–2016, adjusted by country- and band inscription-specific reporting rates. Direct and indirect band recoveries of adult and juvenile male and female black ducks banded in eastern Canada from 1990–2016 were used to estimate age- and sex-specific annual survival rates.

The black duck AHM framework is based on two hypotheses regarding black duck population ecology. The first hypothesis states that black duck population growth is limited by competition with mallards during the breeding season. As the effect of mallard competition ($c2$) increases, black duck productivity decreases which then limits black duck population growth. The second hypothesis states that black duck population growth is limited by harvest because hunting mortality is additive to natural mortality. As the effect of harvest mortality, or additivity ($a1$) increases, annual survival decreases and limits black duck population growth. The current AHM framework incorporates each of these hypotheses into a single parametric (i.e., regression) model. Estimates of each parameter (i.e., mallard competition and additive hunting mortality) are updated annually with the current year's monitoring data (Figure 12) and are used to establish subsequent harvest regulations.

Optimal country-specific regulatory strategies for the 2018 hunting season were calculated for black ducks using: (1) an objective to achieve 98% of the maximum, long-term cumulative harvest; (2) country-specific regulatory alternatives; and (3) the current population model and parameter estimates for mallard competition and additive mortality. The resulting regulatory strategy includes options conditional on the regulatory alternatives selected the previous hunting season. Based on a liberal regulatory alternative selected by Canada and moderate regulatory alternative selected by the United States for the 2017 hunting season, an estimated 2017 breeding population size of 0.54 million black ducks and 0.44 million mallards observed in the core survey area, the optimal regulatory choices for the 2018 hunting season are the liberal regulatory alternative in Canada and the moderate regulatory alternative in the United States (Table 7).

Table 7 – Black duck optimal regulatory strategies[a] for Canada and the United States for the 2018 hunting season predicated on a liberal alternative selected by Canada and a moderate alternative selected by the United States the previous year (2017). This strategy is based on current regulatory alternatives, black duck model, and the objective of achieving 98% of the maximum, long-term cumulative harvest and to share the allocated harvest (i.e., parity) equitably between countries. The shaded cell indicates the regulatory prescription for each country in 2018.

[b] Mallard and black duck breeding population sizes (in millions).

9.2 Northern Pintails

In 2010, the Flyway Councils and the USFWS established an adaptive management framework to inform northern pintail harvest decisions. The current protocol is based on: (1) an explicit harvest management objective; (2) regulatory alternatives that do not permit partial seasons (shorter pintail season within the general duck season) or 3-bird daily bag limits; (3) a formal optimization process using stochastic dynamic programming (Williams et al. 2002); (4) harvest allocation on a national rather than Flyway-by-Flyway basis, with no explicit attempt to achieve a particular allocation of harvest among Flyways; and (5) current system models. Details describing the historical development of the technical and policy elements of the northern pintail adaptive management framework can be found in the northern pintail harvest strategy document (U.S. Fish and Wildlife Service 2010).

The harvest-management objective for the northern pintail population is to maximize long-term cumulative harvest, which inherently requires perpetuation of a viable population. This objective is specified under a constraint that provides for an open hunting season when the observed breeding population is ≥1.75 million birds (based on the lowest observed breeding population size since 1985 of 1.79 million birds in 2002). The single objective and constraint, in conjunction with the regulatory alternatives were determined after an intensive consultation process with the waterfowl management community. The resulting management objective serves to integrate and balance multiple competing objectives for pintail harvest management, including minimizing closed seasons, eliminating partial seasons, maximizing seasons with liberal season length and greater than 1-bird daily bag limit, and minimizing large changes in regulations.

The adaptive management protocol considers a range of regulatory alternatives for pintail harvest management that includes a closed season, 1-bird daily bag limit, or 2-bird daily bag limit. The maximum pintail season length depends on the general duck season framework (characterized as liberal, moderate, or restrictive and varying by Flyway) specified by mallard AHM. An optimal pintail regulation is calculated under the assumption of a liberal mallard season length in all Flyways. However, if the season length of the general duck season determined by mallard AHM is less than liberal in any of the Flyways, then an appropriate pintail daily bag limit would be substituted for that Flyway. Thus, a shorter season length dictated by mallard AHM would result in an equivalent season length for pintails, but with increased bag limit if the expected harvest remained within allowable limits.

Regulatory substitution rules have been developed for the Central and Mississippi Flyways, where the general duck season length is driven by the mid-continent mallard AHM protocol (Table 8). These substitutions were determined by finding a pintail daily bag limit whose expected harvest was less than or equal to that called for under the national recommendation. Thus, if the national pintail harvest strategy called for a liberal 2-bird bag limit, but the mid-continent mallard season length was moderate, the recommended pintail regulation for the Central and Mississippi Flyways would be moderate in length with a 3-bird bag limit. Because season lengths more restrictive than liberal are expected infrequently in the Atlantic and Pacific Flyways under current eastern and western mallard AHM strategies, substitution rules have not yet been developed for these Flyways. If shorter season lengths were called for in the Pacific or Atlantic Flyway, then similar rules would be specified for these Flyways and used to identify the appropriate substitution. In all cases, a substitution produces a lower expected harvest than the harvest allowed under the pintail strategy.

The current AHM protocol for pintails considers two population models. Each model represents an alternative hypothesis about the effect of harvest on population dynamics: one in which harvest is additive to natural mortality, and another in which harvest is compensatory to natural mortality. The compensatory model assumes that the mechanism for compensation is density-dependent post-harvest (winter) survival. The models differ only in how they incorporate the winter survival rate. In the additive model, winter survival rate is a constant, whereas winter survival is density-dependent in the compensatory model. A complete description of the model set used to predict pintail population change can be found in Appendix H. Model weights for the pintail model set have been updated annually since 2007 by comparing model predictions with observed survey results. As of 2017, model weights favor the hypothesis that harvest mortality is additive (57%).

An optimal regulatory strategy for the 2018 hunting season was calculated for northern pintails using: (1) an

Table 8 – Substitution rules in the Central and Mississippi Flyways for joint implementation of northern pintail and mallard harvest strategies. The mid-continent mallard AHM strategy stipulates the maximum season length for pintails in the Central and Mississippi Flyways. The substitutions are used when the mid-continent mallard season length is less than liberal. For example, if the pintail strategy calls for a liberal season length with a 2-bird daily bag limit, but the mid-continent mallard strategy calls for a restrictive season length, the recommended pintail regulation for the Central and Mississippi Flyways would be restrictive in length with a 3-bird daily bag limit.

Pintail	Mid-continent mallard adaptive harvest management season length			
Regulation	Closed	Restrictive	Moderate	Liberal
Closed	Closed	Closed	Closed	Closed
Liberal 1	Closed	Restrictive 3	Moderate 3	Liberal 1
Liberal 2	Closed	Restrictive 3	Moderate 3	Liberal 2

objective to maximize long-term cumulative harvest; (2) current regulatory alternatives and the closed-season constraint; and (3) current population models and model weights. The resulting regulatory strategy includes options conditional on the regulatory alternative selected the previous hunting season (Figure 13). Based on a liberal, 1-bird daily bag limit, regulatory alternative selected for the 2017 hunting season and an estimated 2017 breeding population size of 2.89 million pintails observed at a mean latitude of 56.7 degrees, the optimal regulatory choice for the 2018 hunting season for all four Flyways is the liberal regulatory alternative with a 2-bird daily bag limit (Table 9).

9.3 Scaup

The USFWS implemented an AHM decision-making framework to inform scaup harvest regulations in 2008 (Boomer and Johnson 2007). Prior to the implementation of the SEIS 2013, the scaup AHM protocol first derived optimal harvest levels which were then used to determine the recommended regulatory package. Each year, an optimization was performed to identify the optimal harvest level based on updated scaup population parameters. The harvest regulation was then determined by comparing the optimal harvest level to the harvest thresholds corresponding to restrictive, moderate, and liberal packages (see Boomer et al. 2007). Due to the changes in decision timing associated with the SEIS, these procedures are not possible because decision makers would have to condition their regulatory decision on the harvest levels observed during the previous hunting season and this information would not be available. As a result, the decision variable (harvest) in the scaup optimization was changed from harvest levels to a set of packages with associated expected harvest levels in the updated optimization methods. We used the thresholds identified in Boomer et al. (2007) to specify expected harvest levels for each package (Table 10). To account for partial controllability of the scaup harvest, we assumed that the harvest under each package could be represented with a normal distribution with the mean set to the expected harvest level, assuming a coefficient of variation equal to 20%.

Initial scaup regulatory alternatives associated with restrictive, moderate, and liberal packages were developed based on a simulation of an optimal policy derived under an objective to achieve 95% of the maximum, long-term cumulative harvest (Boomer et al. 2007). This objective resulted in a strategy less sensitive to small changes in population size compared to a strategy derived under an objective to achieve 100% of the maximum, long-term cumulative harvest and allowed for some harvest opportunity at relatively low population sizes. The USFWS worked with the Flyways to specify Flyway-specific regulatory alternatives to achieve the allowable harvest thresholds corresponding to each package. At this time, the USFWS also agreed to consider "hybrid season" options that would be available to all Flyways for the restrictive and moderate packages. Hybrid seasons allow daily bag limits to vary for certain continuous portions of the scaup season length. In 2008, restrictive, moderate, and liberal scaup regulatory alternatives were defined and implemented in all four Flyways. Subsequent feedback from the Flyways led the USFWS to further clarify
Figure 13 – Northern pintail pre-survey harvest policies derived with updated optimization methods that account for changes in decision timing associated with adaptive harvest management protocols specified in the SEIS 2013. This strategy is based on current regulatory alternatives, current population models and their weights, and an objective to maximize long-term cumulative harvest.

Table 9 – Northern pintail optimal regulatory strategy[a] for the 2018 hunting season predicated on a liberal season and a 1-bird daily bag limit selected the previous year (2017). This strategy is based on current regulatory alternatives, northern pintail models and weights, and the objective of maximizing long-term cumulative harvest constrained to provide for an open hunting season when the observed breeding population is ≥1.75 million birds. The shaded cell indicates the regulatory prescription for 2018.

[a] C = closed season, L1 = liberal season with 1-bird daily bag limit, L2 = liberal season with 2-bird daily bag limit.

[b] Observed northern pintail breeding population size (in millions) from the WBPHS (strata 1–18, 20–50, 75–77).

[c] Mean latitude (in degrees) is the average latitude of the WBPHS strata weighted by population size.

Table 10 – Regulatory alternatives[a] and total expected harvest levels corresponding to the closed, restrictive, moderate, and liberal packages considered in the scaup adaptive harvest management decision framework.

Package	Atlantic	Mississippi	Central	Pacific	Expected Harvest[c]
Closed					0.04
Restrictive	20(2)/40(1)[b]	45(2)/15(1)[b]	39(2)/35(1)[b]	86(2)	0.20
Moderate	60(2)	60(3)	74(3)	86(3)	0.35
Liberal	60(4)	60(4)	74(6)	107(7)	0.60

[a] Season length in days (daily bag limit); these alternatives assume an overall liberal adaptive harvest management framework as determined by the status of mallards.

[b] Multiple day and daily bag limit combinations refer to hybrid seasons which allow for different daily bag limits over a continuous season length.

[c] Total harvest in millions (Canada and United States combined).

criteria associated with the establishment of "hybrid seasons" and to allow additional modifications of the alternatives for each Flyway resulting in updated regulatory alternatives that were adopted in 2009. Because of the considerable uncertainty involved with predicting scaup harvest, the USFWS and the Flyways agreed to keep these packages in place for at least 3 years. In 2013, the moderate packages for the Mississippi and Central Flyways were modified to include a 3 bird daily bag limit.

The lack of scaup demographic information over a sufficient time frame and at a continental scale precludes the use of a traditional balance equation to represent scaup population and harvest dynamics. As a result, we used a discrete-time, stochastic, logistic-growth population model to represent changes in scaup abundance, while explicitly accounting for scaling issues associated with the monitoring data. Details describing the modeling and assessment framework that has been developed for scaup can be found in Appendix I and in Boomer and Johnson (2007).

We updated the scaup assessment based on the current model formulation and data extending from 1974 through 2016. As in past analyses, the state-space formulation and Bayesian analysis framework provided reasonable fits to the observed breeding population and total harvest estimates with realistic measures of variation. The posterior mean estimate of the intrinsic rate of increase (r) is 0.15 while the posterior mean estimate of the carrying capacity (K) is 8.42 million birds. The posterior mean estimate of the scaling parameter (q) is 0.69, ranging between 0.61 and 0.77 with 95% probability.

An optimal regulatory strategy for the 2018 hunting season was calculated for scaup using: (1) an objective to achieve 95% of the maximum, long-term cumulative harvest; (2) current regulatory alternatives; and (3) the current population model and updated parameter estimates. The resulting regulatory strategy includes options conditional on the regulatory alternative selected the previous hunting season (Table 11). We simulated the use of this regulatory strategy to determine expected performance characteristics. Assuming that harvest management adhered to this strategy (and that current model parameters accurately reflect population dynamics), breeding-population size would be expected to average 4.76 million (SD = 0.81 million). Based on a moderate regulatory alternative selected for the 2017 hunting season and an estimated 2017 breeding population size of 4.37 million scaup, the optimal regulatory choice for the 2018 hunting season for all four Flyways is the moderate regulatory alternative (see Table 11).

10 EMERGING ISSUES IN ADAPTIVE HARVEST MANAGEMENT

Learning occurs passively with current AHM protocols as annual comparisons of model predictions to observations from monitoring programs are used to update model weights and relative beliefs about system

Table 11 – Scaup optimal regulatory strategy[a] for the 2018 hunting season. This strategy is based on the current scaup population model and an objective to achieve 95% of the maximum, long-term cumulative harvest. Predicated on a moderate regulatory alternative selected the previous year (2017), the shaded cell indicates the regulatory prescription for the 2018 hunting season.

responses to management (Johnson et al. 2002b) or as model parameters are updated based on an assessment of the most recent monitoring data (Boomer and Johnson 2007, Johnson et al. 2007). However, learning can also occur as decision-making frameworks are evaluated to determine if objectives are being achieved, have changed, or if other aspects of the decision problem are adequately being addressed. Often the feedback resulting from this process results in a form of "double-loop" learning (Lee 1993) that offers the opportunity to

adapt decision-making frameworks in response to a shifting decision context, novel or emerging management alternatives, or a need to revise assumptions and models that may perform poorly or need to account for new information. Adaptive management depends on this iterative process to ensure that decision-making protocols remain relevant in evolving biological and social systems. Throughout the waterfowl harvest management community, substantial progress has been made to outline the important issues that must be considered in the revision of each AHM protocol (Johnson et al. 2015). This work has resulted in discussions of the key policy elements of each mallard AHM framework that will be used to guide the biological assessments and technical work associated with revisions to AHM models.

In addition, the HMWG has been discussing the technical challenges involved with dealing with large-scale habitat and environmental change on the decision-making frameworks used to inform waterfowl harvest management. We anticipate that large-scale system change will exacerbate most forms of uncertainty that affect waterfowl AHM, but we believe that the elements of the current AHM framework provide the necessary structure for coping with these changing systems (Nichols et al. 2011).

In response to these large-scale issues, the HMWG has been focusing efforts on the evolving needs of AHM and the role of the working group in planning for and executing the double-loop learning phase of AHM. At its most recent meeting, the HMWG prioritized the technical work for the upcoming 2018–2019 regulations cycle, focusing on the revisions to mallard AHM frameworks (Appendix C).

Appendix A   Harvest Management Working Group Members

This list includes only permanent members of the Harvest Management Working Group. Not listed here are numerous persons from federal and state agencies that assist the Working Group on an ad-hoc basis.

Coordinator:

Scott Boomer

U.S. Fish & Wildlife Service

11510 American Holly Drive

Laurel, Maryland 20708-4017

phone: 301-497-5684; fax: 301-497-5871

e-mail: scott_boomer@fws.gov

USFWS Representatives:

Nanette Seto (Region 1)

U.S. Fish & Wildlife Service

911 NE 11TH Avenue

Portland, OR 97232-4181

phone: 503 231-6159

fax: 503 231-2019

e-mail: nanette_seto@fws.gov

Scott Carleton (Region 2)

U.S. Fish & Wildlife Service

500 Gold SW - 8th Floor

Albuquerque, NM 87103

phone: 505-248-6639

fax: 505-248-7885

e-mail: scott_carleton@fws.gov

Tom Cooper (Region 3)

U.S. Fish & Wildlife Service

5600 American Blvd West

Bloomington, MN 55437-1458

phone: 612-713-5101

fax: 612-713-5393

e-mail: tom_cooper@fws.gov

Laurel Barnhill (Region 4)

U.S. Fish & Wildlife Service

1875 Century Blvd.

Atlanta, GA 30345

phone: 404-679-7188

fax: 404 679-4180

e-mail:laurel_barnhill@fws.gov

Pam Toschik (Region 5)

U.S. Fish & Wildlife Service

300 Westgate Center Drive

Hadley, MA 01035-9589

phone: 413-253-8610

fax: 413-253-8293

e-mail:pam_toschik@fws.gov

Casey Stemler (Region 6)

U.S. Fish & Wildlife Service

P.O. Box 25486-DFC

Denver, CO 80225-0486

Appendix B   2018-2019 Regulatory Schedule

SCHEDULE OF BIOLOGICAL INFORMATION AVAILABILITY, REGULATIONS MEETINGS AND FEDERAL REGISTER PUBLICATIONS FOR THE 2018-19 SEASONS

SURVEY & ASSESSMENT SCHEDULE	MEETING SCHEDULE	FEDERAL REGISTER SCHEDULE
March - June, 2017 *SPRING POPULATION SURVEYS*		June 1, 2017 *PROPOSED RULEMAKING (PRELIMINARY) WITH STATUS INFORMATION and ISSUES*
	June 21, 2017 - Falls Church, VA **SRC Meeting (nonregulatory)**	
August 15, 2017 *WATERFOWL STATUS REPORT*		August 15, 2017 *SUPPLEMENTAL PROPOSALS*
September 1, 2017 *AHM REPORT w/OPTIMAL ALTERNATIVES, WEBLESS and CRANE STATUS* INFORMATION, DOVE and WOODCOCK REGULATORY ALTERNATIVES, and HUNTER ACTIVITY and HARVEST REPORT	August 15 - September 15, 2017 **Flyway Tech And Council Meetings**	
	October 17-18, 2017 - Bloomington, MN **Service Regulations Committee Regulatory Meeting**	
		December 10, 2017 *PROPOSED SEASON FRAMEWORKS* **(30 Day Comment Period)**
December 15, 2017 - January 31, 2018 *FALL and WINTER SURVEY INFORMATION for CRANES and WATERFOWL*	March 2018 (at North Am. Conf) **Flyway Council Mtgs (nonregulatory)**	
		February 25, 2018 *FINAL SEASON FRAMEWORKS*
		June 1, 2018 *ALL HUNTING SEASONS SELECTIONS (Season Selections Due April 30)*
	September 1, 2018 and later **ALL HUNTING SEASONS**	

Figure B.1 – Schedule of biological information availability, regulation meetings, and Federal Register publications for the 2018–2019 hunting season.

Appendix C

2018 Harvest Management Working Group Priorities

Priority rankings and project leads identified for the technical work proposed at the 2016 Harvest Management Working Group meeting.

Highest Priorities (Urgent and Important)

- Adaptive Harvest Management Revisions (*aka, Double-looping*)
  - · Multi-stock management (*Atlantic Flyway, PHAB, HMWG*)
  - · Mid-continent mallard (*Mississippi and Central Flyways, PHAB, others...*)
  - · Western mallard(*Pacific Flyway, PHAB, others...*)
- Re-invigorate institutional support for AHM (*PHAB, and HMWG Communications Team*)

Long-Range Priorities (Non-Urgent, but Very Important)

- Time dependent optimal solutions to address system change (*Scott Boomer, Fred Johnson, Mike Runge*)
  - · Habitat change
  - · Hunter dynamics
  - · Climate change
- Northern pintail AHM Revision (Double-looping) (*Pacific Flyway, PHAB, others...*)
- Consideration of NAWMP objectives for waterfowl management (*HDWG, Flyway Councils, FWS, NAWMP Interim Integration Committee, Joint Technical Committee, others...*)

Additional Priorities

- Waterfowl harvest potential assessment methods case study development (*PHAB, Tech Sections, others...*)
- Canvasback harvest strategy development (*PHAB, Tech Sections, others...*)
- Waterfowl Breeding Population and Habitat Survey Review (*Migratory Bird Surveys Branch, HMWG*)

Appendix D   Mid-continent Mallard Models

In 1995, we developed population models to predict changes in mid-continent mallards based on the traditional survey area which includes individuals from Alaska (Johnson et al. 1997). In 1997, we added mallards from the Great Lakes region (Michigan, Minnesota, and Wisconsin) to the mid-continent mallard stock, assuming their population dynamics were equivalent. In 2002, we made extensive revisions to the set of alternative models describing the population dynamics of mid-continent mallards (Runge et al. 2002, U.S. Fish and Wildlife Service 2002). In 2008, we redefined the population of mid-continent mallards (Table 1) to account for the removal of Alaskan birds (WBPHS strata 1–12) that are now considered to be in the western mallard stock and have subsequently rescaled the model set accordingly.

Mid-continent Mallard Breeding Population Estimates

Model Structure

Collectively, the models express uncertainty (or disagreement) about whether harvest is an additive or compensatory form of mortality (Burnham et al. 1984), and whether the reproductive process is weakly or strongly density-dependent (i.e., the degree to which reproductive rates decline with increasing population size).

All population models for mid-continent mallards share a common "balance equation" to predict changes in breeding-population size as a function of annual survival and reproductive rates:

$$N_{t+1} = N_t \left(m S_{t,AM} + (1 - m)(S_{t,AF} + R_t(S_{t,JF} + S_{t,JM} \phi_F^{sum}/\phi_M^{sum})) \right)$$

where:

N = breeding population size,

m = proportion of males in the breeding population,

S_{AM}, S_{AF}, S_{JF}, and S_{JM} = survival rates of adult males, adult females, young females, and young males, respectively,

R = reproductive rate, defined as the fall age ratio of females,

$\phi_F^{sum}/\phi_M^{sum}$ = the ratio of female (F) to male (M) summer survival, and t = year.

We assumed that m and $\phi_F^{sum}/\phi_M^{sum}$ are fixed and known. We also assumed, based in part on information provided by Blohm et al. (1987), the ratio of female to male summer survival was equivalent to the ratio of annual survival rates in the absence of harvest. Based on this assumption, we estimated $\phi_F^{sum}/\phi_M^{sum} = 0.897$. To estimate m we expressed the balance equation in matrix form:

$$\begin{bmatrix} N_{t+1,AM} \\ N_{t+1,AF} \end{bmatrix} = \begin{bmatrix} S_{AM} & RS_{JM}\phi_F^{sum}/\phi_M^{sum} \\ 0 & S_{AF} + RS_{JF} \end{bmatrix} \begin{bmatrix} N_{t,AM} \\ N_{t,AF} \end{bmatrix}$$

and substituted the constant ratio of summer survival and means of estimated survival and reproductive rates. The right eigenvector of the transition matrix is the stable sex structure that the breeding population eventually would attain with these constant demographic rates. This eigenvector yielded an estimate of $m = 0.5246$.

Using estimates of annual survival and reproductive rates, the balance equation for mid-continent mallards over-predicted observed population sizes by 11.0% on average. The source of the bias is unknown, so we modified the balance equation to eliminate the bias by adjusting both survival and reproductive rates:

Table D.1 – Estimates (N) and associated standard errors (SE) of mid-continent mallards (in millions) observed in the WBPHS (strata 13–18, 20–50, and 75–77) and the Great Lakes region (Michigan, Minnesota, and Wisconsin) from 1992 to 2017.

Year	WBPHS area		Great Lakes region		Total	
	N	SE	N	SE	N	SE
1992	5.6304	0.2379	0.9964	0.1178	6.6267	0.2654

2013	10.0335	0.3586	0.7628	0.0744	10.7963	0.3662
2014	10.3989	0.3429	0.6459	0.0681	11.0448	0.3496
2015	11.1724	0.3582	0.6202	0.0514	11.7926	0.3619
2016	11.2083	0.3615	0.6854	0.0705	11.8938	0.3683
2017	9.9500	0.3298	0.6927	0.0523	10.6427	0.3339

$$N_{t+1} = \gamma_S N_t \left(mS_{t,am} + (1-m)\left(S_{t,AF} + \gamma_R R_t \left(S_{t,JF} + S_{t,JM}\phi_F^{sum}/\phi_M^{sum}\right)\right)\right)$$

where γ denotes the bias-correction factors for survival (S), and reproduction (R). We used a least squares approach to estimate $\gamma_S = 0.9407$ and $\gamma_R = 0.8647$.

Survival Process

We considered two alternative hypotheses for the relationship between annual survival and harvest rates. For both models, we assumed that survival in the absence of harvest was the same for adults and young of the same sex. In the model where harvest mortality is additive to natural mortality:

$$S_{t,sex,age} = S_{0,sex}^A (1 - K_{t,sex,age})$$

and in the model where changes in natural mortality compensate for harvest losses (up to some threshold):

$$S_{t,sex,age} = \begin{cases} s_{0,sex}^C & if \ K_{t,sex,age} \leq 1 - s_{0,sex}^C \\ 1 - K_{t,sex,age} & if \ K_{t,sex,age} > 1 - s_{0,sex}^C \end{cases}$$

where s_0 = survival in the absence of harvest under the additive (A) or compensatory (C) model, and K = harvest rate adjusted for crippling loss (20%, Anderson and Burnham 1976). We averaged estimates of s_0 across banding reference areas by weighting by breeding-population size. For the additive model, $s_0 = 0.7896$ and 0.6886 for males and females, respectively. For the compensatory model, $s_0 = 0.6467$ and 0.5965 for males and females, respectively. These estimates may seem counterintuitive because survival in the absence of harvest should be the same for both models. However, estimating a common (but still sex-specific) s_0 for both models leads to alternative models that do not fit available band-recovery data equally well. More importantly, it suggests that the greatest uncertainty about survival rates is when harvest rate is within the realm of experience. By allowing s_0 to differ between additive and compensatory models, we acknowledge that the greatest uncertainty about survival rate is its value in the absence of harvest (i.e., where we have no experience).

Reproductive Process

Annual reproductive rates were estimated from age ratios in the harvest of females, corrected using a constant estimate of differential vulnerability. Predictor variables were the number of ponds in May in Prairie Canada (P, in millions) and the size of the breeding population (N, in millions). We estimated the best-fitting linear model, and then calculated the 80% confidence ellipsoid for all model parameters. We chose the two points on this ellipsoid with the largest and smallest values for the effect of breeding-population size, and generated a weakly density-dependent model:

$$R_t = 0.7166 + 0.1083P_t - 0.0373N_t$$

and a strongly density-dependent model:

$$R_t = 1.1390 + 0.1376P_t - 0.1131N_t$$

Predicted recruitment was then rescaled to reflect the current definition of mid-continent mallards which now excludes birds from Alaska but includes mallards observed in the Great Lakes region.

Pond Dynamics

We modeled annual variation in Canadian pond numbers as a first-order autoregressive process. The estimated model was:

$$P_{t+1} = 2.2127 + 0.3420P_t + \varepsilon_t$$

where ponds are in millions and ε_t is normally distributed with mean $= 0$ and variance $= 1.2567$.

Variance of Prediction Errors

Using the balance equation and sub-models described above, predictions of breeding-population size in year *t+1* depend only on specification of population size, pond numbers, and harvest rate in year *t*. For the period in which comparisons were possible, we compared these predictions with observed population sizes.

We estimated the prediction-error variance by setting:

$$e_t = \ln\left(N_t^{obs}\right) - \ln\left(N_t^{pre}\right)$$

$$e_t \sim N\left(0, \sigma^2\right)$$

$$\hat{\sigma^2} = \sum_t \left[\ln\left(N_t^{obs}\right) - \ln\left(N_t^{pre}\right)\right]^2 / (n-1)$$

where N^{obs} and N^{pre} are observed and predicted population sizes (in millions), respectively, and $n =$ the number of years being compared. We were concerned about a variance estimate that was too small, either by chance or because the number of years in which comparisons were possible was small. Therefore, we calculated the upper 80% confidence limit for σ^2 based on a Chi-squared distribution for each combination of the alternative survival and reproductive sub-models, and then averaged them. The final estimate of σ^2 was 0.0280, equivalent to a coefficient of variation of about 16.85%.

Model Implications

The population model with additive hunting mortality and weakly density-dependent recruitment (SaRw) leads to the most conservative harvest strategy, whereas the model with compensatory hunting mortality and strongly density-dependent recruitment (ScRs) leads to the most liberal strategy. The other two models (SaRs and ScRw) lead to strategies that are intermediate between these extremes. Under the models with compensatory hunting mortality (ScRs and ScRw), the optimal strategy is to have a liberal regulation regardless of population size or number of ponds because at harvest rates achieved under the liberal alternative, harvest has no effect on population size. Under the strongly density-dependent model (ScRs), the density dependence regulates the population and keeps it within narrow bounds. Under the weakly density dependent model (ScRw), the density-dependence does not exert as strong a regulatory effect, and the population size fluctuates more.

Model Weights

Model weights are calculated as Bayesian probabilities, reflecting the relative ability of the individual alternative models to predict observed changes in population size. The Bayesian probability for each model is a function of the models previous (or prior) weight and the likelihood of the observed population size under that model. We used Bayes' theorem to calculate model weights from a comparison of predicted and observed population sizes for the years 1996–2017, starting with equal model weights in 1995.

Appendix E   Eastern Mallard Models

Eastern mallard population dynamics are represented by 4 alternative models that combine two mortality (additive versus compensatory) and two reproductive (strong or weak density dependent) hypotheses. Each balance equation also includes a bias-correction term applied to the reproductive sub-models. In 2017, the removal of stratum 54 from the eastern mallard stock necessitated updating the parameters of the recruitment model and the estimates of the prediction variance. These updated parameter values are described below.

Eastern Mallard Breeding Population Estimates

Table E.1 – Estimates (N) and associated standard errors (SE) of eastern mallards (in millions) observed in the northeastern United States (AFBWS) and southern Ontario and Quebec (WBPHS strata 51–53 and 56) from 1990 to 2017.

[a] Estimates for southern Ontario and Quebec (WBPHS strata 51–53 and 56) were not available in 2013.

Model Structure

As with mid-continent mallards, all population models for eastern mallards share a common balance equation to predict changes in breeding-population size as a function of annual survival and reproductive rates:

$$N_{t+1} = N_t \left((pS_t^{am}) + \left((1-p)\, S_t^{af} \right) + (p\,(A_t^m/d)\, S_t^{ym}) + \left(p\,(A_t^m/d)\, \psi S_t^{yf} \right) \right)$$

where:

N = breeding-population size,

p = proportion of males in the breeding population,

S^{am}, S^{af}, S^{ym}, and S^{yf} = survival rates of adult males, adult females, young males, and young females, respectively,

A^m = ratio of young males to adult males in the harvest,

d = ratio of young male to adult male direct recovery rates,

ψ = the ratio of male to female summer survival, and t = year.

In this balance equation, we assume that p, d, and ψ are fixed and known. The parameter ψ is necessary to account for the difference in anniversary date between the breeding-population survey (May) and the survival and reproductive rate estimates (August). This model also assumes that the sex ratio of fledged young is 1:1; hence A^m/d appears twice in the balance equation. We estimated $d = 1.043$ as the median ratio of young:adult male band-recovery rates in those states from which wing receipts were obtained. We estimated $\psi = 1.216$ by regressing through the origin estimates of male survival against female survival in the absence of harvest, assuming that differences in natural mortality between males and females occur principally in summer. To estimate p, we used a population projection matrix of the form:

$$\begin{bmatrix} M_{t+1} \\ F_{t+1} \end{bmatrix} = \begin{bmatrix} S^{am} + (A^m/d)\, S^{ym} & 0 \\ (A^m/d)\, \psi S^{yf} & S^{af} \end{bmatrix} \begin{bmatrix} M_t \\ F_t \end{bmatrix}$$

where M and F are the relative number of males and females in the breeding populations, respectively. To parameterize the projection matrix we used average annual survival rate and age ratio estimates, and the estimates of d and ψ provided above. The right eigenvector of the projection matrix is the stable proportion of males and females the breeding population eventually would attain in the face of constant demographic rates. This eigenvector yielded an estimate of $p = 0.544$.

During the 2002 eastern mallard model set revision, bias-correction terms for the eastern mallard balance equation assumed that any bias resided solely in survival rates:

$$N_{t+1} = N_t \omega \left(pS_t^{am} + \left((1-p)\, S_t^{af} \right) + (p\,(A_t^m/d)\, S_t^{ym}) + \left(p\,(A_t^m/d)\, \psi S_t^{yf} \right) \right)$$

(where ω is the bias-correction factor for survival rates), or solely in reproductive rates:

$$N_{t+1} = N_t \left(pS_t^{am} + \left((1-p)\, S_t^{af} \right) + (p\alpha\,(A_t^m/d)\, S_t^{ym}) + \left(p\alpha\,(A_t^m/d)\, \psi S_t^{yf} \right) \right)$$

(where α is the bias-correction factor for reproductive rates). These analyses resulted in least squares estimates of $\omega = 0.836$ and $\alpha = 0.701$, suggesting a positive bias in survival or reproductive rates. The 2011 updates of eastern mallard model weights indicated strong support for models that account for bias in eastern

mallard demographic parameters; models without bias-corrections for survival or recruitment accumulated weights of approximately zero (U.S. Fish and Wildlife Service 2011). To simplify the updated model set, we eliminated the no-bias and survival bias models. Although, the predictions from the recruitment and survival bias-corrected sub models did not differ substantially, models that included bias in recruitment had slightly higher weights. Consequently, we retained the bias-correction term for recruitment in the eastern mallard model set.

Survival Process

During the eastern mallard model assessment, it was noted that observed survival rates of eastern mallards varied from year to year, but did not display an obvious trend, while harvest rates have generally declined since 2002 (U.S. Fish and Wildlife Service 2011). Given the uncertainty in predicting eastern mallard survival rates from an additive harvest mortality model, we chose to include an alternative survival model that represents compensatory harvest mortality. For both models, we assumed that survival in the absence of harvest was the same for adults and young of the same sex. In the model where harvest mortality is additive to natural mortality:

$$S_{t,sex,age} = S_{0,sex}^A (1 - K_{t,sex,age})$$

and in the model where changes in natural mortality compensate for harvest losses (up to some threshold):

$$S_{t,sex,age} = \begin{cases} s_{0,sex}^C & if\ K_{t,sex,age} \leq 1 - s_{0,sex}^C \\ 1 - K_{t,sex,age} & if\ K_{t,sex,age} > 1 - s_{0,sex}^C \end{cases}$$

where s_0 = survival in the absence of harvest under the additive (A) or compensatory (C) model, and K = harvest rate adjusted for crippling loss (20%, Anderson and Burnham 1976).

Because we did not have current estimates to parameterize the compensatory relationship between kill rates and annual survival for eastern mallards, we chose to use the mid-continent mallard compensatory survival parameters scaled to observed eastern mallard survival estimates. Mid-continent mallard additive survival parameters are approximately 7.5% higher than male and 14% higher than female eastern mallard estimates. To make the mid-continent compensatory parameters comparable to eastern mallards, we scaled the mid-continent mallard compensatory survival parameters by the same amount. Therefore, the compensatory model parameters ($s_{0,sex}^C$) for mid-continent mallards were scaled from 0.6467 to 0.5985 for males and from 0.5965 to 0.5154 for females for use in the eastern mallard model set. We used the same parameter values for the additive harvest mortality model ($s_{0,sex}^A = 0.7307$ for males and 0.5950 for females)that were estimated for the 2002 revision.

Reproductive Process

As with survival, annual reproductive rates must be predicted in advance of setting regulations. We relied on the apparent relationship between breeding-population size and reproductive rates:

$$R_t = ae^{bN_t}$$

where R_t is the reproductive rate (i.e., A_t^m/d), N_t is breeding-population size in millions, and a and b are model parameters. The least-squares parameter estimates were $a = 2.514$ and $b = -0.888$. Because of both the importance and uncertainty of the relationship between population size and reproduction, we specified two alternative models in which the slope (b) was fixed at the least-squares estimate $\pm$ one standard error, and in which the intercepts (a) were subsequently re-estimated. This provided alternative hypotheses of strongly density-dependent ($a = 4.4651$, $b = -1.4601$) and weakly density-dependent reproduction ($a = 1.5824$, $b = -0.4273$).

Variance of Prediction Errors

Using the balance equations and sub-models provided above, predictions of breeding-population size in year *t+1* depend only on the specification of a regulatory alternative and on an estimate of population size in year *t*. We were interested in how well these predictions corresponded with observed population sizes. In making these comparisons, we were primarily concerned with how well the bias-corrected balance equations and reproductive and survival sub-models performed. Rather than use regulations as model inputs, we used estimates of harvest rates for the period in which reliable estimates of harvest rates were available (2002–2016).

We estimated the prediction-error variance by setting:

$$e_t = \ln\left(N_t^{obs}\right) - \ln\left(N_t^{pre}\right)$$

$$\text{then assuming} \quad e_t \sim N\left(0, \sigma^2\right)$$

$$\text{and estimating} \quad \hat{\sigma}^2 = \sum_t \left[\ln\left(N_t^{obs}\right) - \ln\left(N_t^{pre}\right)\right]^2 / (n-1)$$

where N^{obs} and N^{pre} are observed and predicted population sizes (in millions), respectively, and $n = 9$. We were concerned about a variance estimate that was too small, either by chance or because the number of years in which comparisons were possible was small. Therefore, we calculated the upper 80% confidence limit for σ^2 based on a Chi-squared distribution for each combination of the alternative survival and reproductive sub-models, and then averaged them. The final estimate of σ^2 was 0.0450, equivalent to a coefficient of variation of about 21%.

Model Implications

The population model with additive hunting mortality and weakly density-dependent recruitment (SaRw) leads to the most conservative harvest strategy, whereas the model with compensatory hunting mortality and strongly density-dependent recruitment (ScRs) leads to the most liberal strategy. The other two models (SaRs and ScRw) lead to strategies that are intermediate between these extremes. Under the models with compensatory hunting mortality (ScRs and ScRw), the optimal strategy is to have a liberal regulation regardless of population size because at harvest rates achieved under the liberal alternative, harvest has no effect on population size. Under the strongly density-dependent model (ScRs), the density dependence regulates the population and keeps it within narrow bounds. Under the weakly density dependent model (ScRw), density-dependence does not exert as strong a regulatory effect, and the population size fluctuates more.

Model Weights

We used Bayes' theorem to calculate model weights from a comparison of predicted and observed population sizes for the years 2003–2017. We calculated weights for the alternative models based on an assumption of equal model weights in 2002 (the last year data was used to develop most model components) and on estimates of year-specific harvest rates (Appendix G).

Appendix F   Western Mallard Models

In contrast to mid-continent and eastern mallards, we did not model changes in population size for both the Alaska and southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined) substocks of western mallards as an explicit function of survival and reproductive rate estimates (which in turn may be functions of harvest and environmental covariates). We believed this so-called "balance-equation approach" was not viable for western mallards because of insufficient banding in Alaska to estimate survival rates, and because of the difficulty in estimating substock-specific fall age ratios from a sample of wings derived from a mix of breeding stocks.

Western Mallard Breeding Population Estimates

Table F.1 – Estimates (N) and associated standard errors (SE) of western mallards (in millions) observed in Alaska (WBPHS strata 1–12) and the southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined) from 1990 to 2017.

[a] Available California survey estimates begin in 1992; Oregon surveys estimates begin in 1994 and were unavailable in 2001.

[b] Southern Pacific Flyway includes California, Oregon, Washington, and British Columbia observations.

Model Structure

To evaluate western mallard population dynamics, we used a discrete logistic model (Schaefer 1954), which combines reproduction and natural mortality into a single parameter r, the intrinsic rate of growth. The model assumes density-dependent growth, which is regulated by the ratio of population size, N, to the carrying capacity of the environment, K (i.e., equilibrium population size in the absence of harvest). In the traditional formulation, harvest mortality is additive to other sources of mortality, but compensation for hunting losses can occur through subsequent increases in production. However, we parameterized the model in a way that also allows for compensation of harvest mortality between the hunting and breeding seasons. It is important to note that compensation modeled in this way is purely phenomenological, in the sense that there is no explicit ecological mechanism for compensation (e.g., density-dependent mortality after the hunting season). The basic model for both the Alaska and southern Pacific Flyway substocks has the form:

$$N_{t+1} = \left[N_t + N_t r \left(1 - \frac{N_t}{K} \right) \right] (1 - \alpha_t)$$

where,

$$\alpha_t = d h_t^{AM}$$

and where t = year, h^{AM} = the harvest rate of adult males, and d = a scaling factor. The scaling factor is used to account for a combination of unobservable effects, including un-retrieved harvest (i.e., crippling loss), differential harvest mortality of cohorts other than adult males, and for the possibility that some harvest mortality may not affect subsequent breeding-population size (i.e., the compensatory mortality hypothesis).

Estimation Framework

We used Bayesian estimation methods in combination with a state-space model that accounts explicitly for both process and observation error in breeding population size. This combination of methods is becoming widely used in natural resource modeling, in part because it facilitates the fitting of non-linear models that may have non-normal errors (Meyer and Millar 1999). The Bayesian approach also provides a natural and intuitive way to portray uncertainty, allows one to incorporate prior information about model parameters, and permits the updating of parameter estimates as further information becomes available. Breeding population data are available for California and Oregon from 1994-2017 (except for 2001), British Columbia from 2006–2017, and Washington from 2010–2017. We attempted to use correlations with adjacent states to impute data back to 1992 for WA and BC, but could not find a reasonable correlation between those surveys and other regions (potentially due to a short time series). Therefore, we imputed population estimates for BC and WA by sampling values from the mean and variance within the MCMC framework. Specifically, we calculated the total mean and variance of breeding population sizes based on observed data (2006–2017 for British Columbia, and 2010–2016 for Washington), and then used those means and variances to sample a population size for the missing years (1992-2005 for British Columbia; and 1992-2009 for Washington) during each iteration of MCMC sampling. Although this approach imputes values based on a random draw, it does acknowledge added uncertainty in those estimates compared to the years with observed data. Further, given the low annual variability and lack of trend, we have no evidence that the recent survey estimates used to generate the mean and variance are not a reasonable approximation of historical breeding population sizes.

We first scaled N by K as recommended by Meyer and Millar (1999), and assumed that process errors were log-normally distributed with mean 0 and variance σ^2. Thus, the process model had the form:

$$
\begin{aligned}
P_t &= N_t/K_t \\
\log(P_t) &= \log\left([P_{t-1} + P_{t-1} r (1 - P_{t-1})] \left(1 - d h_{t-1}^{AM}\right) \right) + e_t
\end{aligned}
$$

where,

$$e_t \sim N(0, \sigma^2)$$

The observation model related the unknown population sizes $(P_t K)$ to the population sizes (N_t) estimated from the breeding-population surveys in Alaska and southern Pacific Flyway. We assumed that the observation process yielded additive, normally distributed errors, which were represented by:

$$N_t = P_t K + \varepsilon_t^{BPOP},$$

where,

$$\varepsilon_t^{BPOP} \sim N(0, \sigma_{BPOP}^2).$$

permitting us to estimate the process error, which reflects the inability of the model to completely describe changes in population size. The process error reflects the combined effect of misspecification of an appropriate model form, as well as any un-modeled environmental drivers. We initially examined a number of possible environmental covariates, including the Palmer Drought Index in California and Oregon, spring temperature in Alaska, and the El Niño Southern Oscillation Index (http://www.cdc.noaa.gov/people/klaus.wolter/MEI/mei.html). While the estimated effects of these covariates on r or K were generally what one would expect, they were never of sufficient magnitude to have a meaningful effect on optimal harvest strategies. We therefore chose not to further pursue an investigation of environmental covariates, and posited that the process error was a sufficient surrogate for these un-modeled effects. Parameterization of the models also required measures of harvest rate. Beginning in 2002, harvest rates of adult males were estimated directly from the recovery of reward bands. Prior to 1993, we used direct recoveries of standard bands, corrected for band-reporting rates provided by Nichols et al. (1995b). We also used the band-reporting rates provided by Nichols et al. (1995b) for estimating harvest rates in 1994 and 1995, except that we inflated the reporting rates of full-address and toll-free bands based on an unpublished analysis by Clint Moore and Jim Nichols (Patuxent Wildlife Research Center). We were unwilling to estimate harvest rates for the years 1996–2001 because of suspected, but unknown, increases in the reporting rates of all bands. For simplicity, harvest rate estimates were treated as known values in our analysis, although future analyses might benefit from an appropriate observation model for these data.

In a Bayesian analysis, one is interested in making probabilistic statements about the model parameters (θ), conditioned on the observed data. Thus, we are interested in evaluating $P(\theta | data)$, which requires the specification of prior distributions for all model parameters and unobserved system states (θ) and the sampling distribution (likelihood) of the observed data $P(data | \theta)$. Using Bayes theorem, we can represent the posterior probability distribution of model parameters, conditioned on the data, as:

$$P(\theta | data) \propto P(\theta) \times P(data | \theta)$$

Accordingly, we specified prior distributions for model parameters r, K, d, and P_0, which is the initial population size relative to carrying capacity. For both substocks, we specified the following prior distributions for r, d, and σ^2:

$$
\begin{aligned}
r &\sim Lognormal(-1.0397, 0.69315) \\
d &\sim Uniform(0, 2) \\
\sigma^2 &\sim Inverse-gamma(0.001, 0.001)
\end{aligned}
$$

The prior distribution for r is centered at 0.35, which we believe to be a reasonable value for mallards based on life-history characteristics and estimates for other avian species. Yet the distribution also admits considerable uncertainty as to the value of r within what we believe to be realistic biological bounds. As for the harvest-rate scalar, we would expect $d \geq 1$ under the additive hypothesis and $d < 1$ under the compensatory hypothesis. As we had no data to specify an informative prior distribution, we specified a vague prior in which d could take on a wide range of values with equal probability. We used a traditional, uninformative prior distribution for σ^2. Prior distributions for K and P_0 were substock-specific and are described in the following sections.

We used the public-domain software JAGS (`https://sourceforge.net/projects/mcmc-jags`) to derive samples from the joint posterior distribution of model parameters via MCMC simulations. We obtained 800,000 samples from the joint posterior distribution, discarded the first 700,000, and then thinned the remainder by 50, resulting in a sample of 2,000 for each of 5 chains, or 10,000 total samples.

Alaska mallards

Data selection—Breeding population estimates of mallards in Alaska (and the Old Crow Flats in Yukon) are available since 1955 in WBPHS strata 1–12 (Smith 1995). However, a change in survey aircraft in 1977 instantaneously increased the detectability of waterfowl, and thus population estimates (Hodges et al. 1996). Moreover, there was a rapid increase in average annual temperature in Alaska at the same time, apparently tied to changes in the frequency and intensity of El Niño events (`http://www.cdc.noaa.gov/people/klaus.wolter/MEI/mei.html`). This confounding of changes in climate and survey methods led us to truncate the years 1955–1977 from the time series of population estimates.

Modeling of the Alaska substock also depended on the availability of harvest-rate estimates derived from band-recovery data. Unfortunately, sufficient numbers of mallards were not banded in Alaska prior to 1990. A search for covariates that would have allowed us to make harvest-rate predictions for years in which band-recovery data were not available was not fruitful, and we were thus forced to further restrict the time series to 1990 and later. Even so, harvest rate estimates were not available for the years 1996–2001, 2014, and 2016 because of unknown changes in band-reporting rates or lack of banding data. Because available estimates of harvest rate showed no apparent variation over time, we simply used the mean and standard deviation of the available estimates and generated independent samples of predictions for the missing years based on a logit transformation and an assumption of normality:

$$ln\left(\frac{h_t}{1-h_t}\right) \sim Normal(-2.4193, 0.0789) \quad \text{for } t = 1996\text{--}2001, \ 2014, \text{ and } 2016.$$

Prior distributions for K and P_0—We believed that sufficient information was available to use mildly informative priors for K and P_0. In recent years the Alaska substock has contained approximately 0.8 million mallards. If harvest rates have been comparable to that necessary to achieve maximum sustained yield (MSY) under the logistic model (i.e., $r/2$), then we would expect $K \approx 1.6$ million. On the other hand, if harvest rates have been less than those associated with MSY, then we would expect $K < 1.6$ million. Because we believed it was not likely that harvest rates were $> r/2$, we believed the likely range of K to be 0.8–1.6 million. We therefore specified a prior distribution that had a mean of 1.4 million, but had a sufficiently large variance to admit a wide range of possible values:

$$K \sim Lognormal(0.13035, 0.41224)$$

Extending this line of reasoning, we specified a prior distribution that assumed the estimated population size of approximately 0.4 million at the start of the time-series (i.e., 1990) was 20–60% of K. Thus on a log scale:

$$P_o \sim Uniform(-1.6094, -0.5108)$$

Parameter estimates—The logistic model and associated posterior parameter estimates provided a reasonable fit to the observed time-series of population estimates. The posterior means of K and r were similar to their priors, although their variances were considerably smaller (Table F.2). However, the posterior distribution of d was essentially the same as its prior, reflecting the absence of information in the data necessary to reliably estimate this parameter.

Table F.2 – Estimates of model parameters resulting from fitting a discrete logistic model to a time-series of estimated population sizes and harvest rates of mallards breeding in Alaska from 1990 to 2017.

Parameter	Mean	SD	2.5% CI[a]	Median	97.5% CI
K	1.088	0.301	0.654	1.034	1.796
P_0	0.354	0.096	0.209	0.343	0.560
d	1.275	0.499	0.198	1.354	1.971
r	0.312	0.119	0.102	0.305	0.563
σ^2	0.022	0.010	0.009	0.020	0.047

[a] CI = credible interval.

Southern Pacific Flyway (CA-OR-WA-BC) mallards

Data selection—Breeding-population estimates of mallards in California are available starting in 1992, but not until 1994 in Oregon. Also, Oregon did not conduct a survey in 2001. To avoid truncating the time series, we used the admittedly weak relationship ($P = 0.04$) between California-Oregon population estimates to predict population sizes in Oregon in 1992, 1993, and 2001. The fitted linear model was:

$$N_t^{OR} = 60103 + 0.0907(N_t^{CA})$$

To derive realistic standard errors, we assumed that the predictions had the same mean coefficient of variation as the years when surveys were conducted ($n = 22$, CV $= 0.088$). The estimated sizes and variances of the southern Pacific Flyway substock were calculated by simply summing the state-specific estimates.

We pooled band-recovery data for the southern Pacific Flyway substock and estimated harvest rates in the same manner as that for Alaska mallards. Although banded sample sizes were sufficient in all years, harvest rates could not be estimated for the years 1996–2001 because of unknown changes in band-reporting rates. As with Alaska, available estimates of harvest rate showed no apparent trend over time, and we simply used the mean and standard deviation of the available estimates and generated independent samples of predictions for the missing years based on a logit transformation and an assumption of normality:

$$ln\left(\frac{h_t}{1 - h_t}\right) \sim Normal(-1.8652, 0.0282) \quad \text{for } t = 1996\text{–}2001$$

Prior distributions for K and P_0—Unlike the Alaska substock, the California-Oregon population has been relatively stable with a mean of 0.48 million mallards. We believed K should be in the range 0.48–0.96 million, assuming the logistic model and that harvest rates were $\leq r/2$. The addition of Washington and British Columbia mallards to the southern Pacific Flyway substock did not result in substantive changes to historically stable population dynamics, but increased the overall size of the southern Pacific Flyway population by approximately 30%. Therefore, we scaled the prior to increase the expected carrying capacity by 30%. We therefore specified a prior distribution on K that had a mean of 0.7 million, but with a variance sufficiently large to admit a wide range of possible values:

$$K \sim Lognormal(-0.2262, 0.2638)$$

The estimated size of the California-Oregon substock was 0.47 million at the start of the time-series (i.e., California plus the imputed Oregon estimate in 1992). We used a similar line of reasoning as that for Alaska for specifying a prior distribution P_0, positing that initial population size was 40-100% of K. Thus on a log scale:

$$P_o \sim Uniform(-0.9163, 0.0)$$

Parameter estimates—The logistic model and associated posterior parameter estimates provided a reasonable fit to the observed time series of population estimates. The posterior means of K and r were similar to their priors, although the variances were considerably smaller (Table F.3). Interestingly, the posterior mean of d was < 1, suggestive of a compensatory response to harvest; however the standard deviation of the estimate was large, with the upper 95% credibility limit > 1.

Table F.3 – Estimates of model parameters resulting from fitting a discrete logistic model to a time-series of estimated population sizes and harvest rates of mallards breeding in the southern Pacific Flyway (California, Oregon, Washington, and British Columbia combined) from 1992 to 2017.

Parameter	Mean	SD	2.5% CI[a]	Median	97.5% CI
K	0.929	0.245	0.602	0.869	1.506
P_0	0.722	0.164	0.425	0.731	0.985
d	0.668	0.401	0.082	0.595	1.647
r	0.276	0.178	0.056	0.233	0.736
σ^2	0.009	0.006	0.002	0.008	0.024

[a] CI = credible interval.

For each western mallard substock, we further summarized the simulation results for r, K, and the scaling factor d to admit parametric uncertainty with a formal correlation structure within the optimization procedure used to calculate the harvest strategy. We first defined a joint distribution for 3 discrete outcomes for each of the 3 population parameters. We used the 30 and 70 percent quantiles for each parameter as the cut points to define three bins for which to discretize 3 values of each posterior distribution. We then determined the frequency of occurrence of each of the 27 possible combinations of each parameter value falling within the 3 bins from the MCMC simulation results. These frequencies were then assigned parameter values based on the midpoint of bin ranges (15, 50, 85 percent quantiles) to specify the joint distribution of the population parameter values used in the optimization.

Appendix G   Modeling Mallard Harvest Rates

Mid-continent

We modeled harvest rates of mid-continent mallards within a Bayesian hierarchical framework. We developed a set of models to predict harvest rates under each regulatory alternative as a function of the harvest rates observed under the liberal alternative, using historical information. We modeled the probability of regulation-specific harvest rates (h) based on normal distributions with the following parameterizations:

$$\text{Closed:} \quad p(h_C) \sim N(\mu_C, \nu_C^2)$$
$$\text{Restrictive:} \quad p(h_R) \sim N(\mu_R, \nu_R^2)$$
$$\text{Moderate:} \quad p(h_M) \sim N(\mu_M, \nu_M^2)$$
$$\text{Liberal:} \quad p(h_L) \sim N(\mu_L, \nu_L^2)$$

For the restrictive and moderate alternatives we introduced the parameter γ to represent the relative difference between the harvest rate observed under the liberal alternative and the moderate or restrictive alternatives. Based on this parameterization, we are making use of the information that has been gained (under the liberal alternative) and are modeling harvest rates for the restrictive and moderate alternatives as a function of the mean harvest rate observed under the liberal alternative. For the harvest-rate distributions assumed under the restrictive and moderate regulatory alternatives, we specified that γ_R and γ_M are equal to the prior estimates of the predicted mean harvest rates under the restrictive and moderate alternatives divided by the prior estimates of the predicted mean harvest rates observed under the liberal alternative. Thus, these parameters act to scale the mean of the restrictive and moderate distributions in relation to the mean harvest rate observed under the liberal regulatory alternative. We also considered the marginal effect of framework-date extensions under the moderate and liberal alternatives by including the parameter δ_f.

To update the probability distributions of harvest rates realized under each regulatory alternative, we first needed to specify a prior probability distribution for each of the model parameters. These distributions represent prior beliefs regarding the relationship between each regulatory alternative and the expected harvest rates. We used a normal distribution to represent the mean and a scaled inverse-chi-square distribution to represent the variance of the normal distribution of the likelihood. For the mean (μ) of each harvest-rate distribution associated with each regulatory alternative, we use the predicted mean harvest rates provided in (U.S. Fish and Wildlife Service 2000, 13–14), assuming uniformity of regulatory prescriptions across Flyways. We set prior values of each standard deviation (ν) equal to 20% of the mean (CV = 0.2) based on an analysis by Johnson et al. (1997). We then specified the following prior distributions and parameter values under each regulatory package:

Closed (in U.S. only):

$$p(\mu_C) \sim N\left(0.0088, \frac{0.0018^2}{6}\right)$$
$$p(\nu_C^2) \sim Scaled\ Inv - \chi^2(6, 0.0018^2)$$

These closed-season parameter values are based on observed harvest rates in Canada during the 1988–93 seasons, which was a period of restrictive regulations in both Canada and the United States.

For the restrictive and moderate alternatives, we specified that the standard error of the normal distribution of the scaling parameter is based on a coefficient of variation for the mean equal to 0.3. The scale parameter of the inverse-chi-square distribution was set equal to the standard deviation of the harvest rate mean under the restrictive and moderate regulation alternatives (i.e., CV = 0.2).

Restrictive:

$$p(\gamma_R) \sim N\left(0.51, \frac{0.15^2}{6}\right)$$

$$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.0133^2)$$

Moderate:

$$p(\gamma_M) \sim N\left(0.85, \frac{0.26^2}{6}\right)$$

$$p(\nu_r^2) \sim Scaled\,Inv - \chi^2(6, 0.0223^2)$$

Liberal:

$$p(\mu_L) \sim N\left(0.1305, \frac{0.0261^2}{6}\right)$$

$$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.0261^2)$$

The prior distribution for the marginal effect of the framework-date extension was specified as:

$$p(\delta_f) \sim N\left(0.02, 0.01^2\right)$$

The prior distributions were multiplied by the likelihood functions based on the last 19 years of data under liberal regulations, and the resulting posterior distributions were evaluated with Markov Chain Monte Carlo simulation. Posterior estimates of model parameters and of annual harvest rates are provided in Table G.1.

Table G.1 – Parameter estimates for predicting mid-continent mallard harvest rates resulting from a hierarchical, Bayesian analysis of mid-continent mallard band-recovery information from 1998 to 2016.

			h_{2016}	0.1109	0.0070

Eastern

We modeled harvest rates of eastern mallards using the same parameterizations as those for mid-continent mallards:

$$\begin{aligned}
\text{Closed:} \quad & p(h_C) \sim N(\mu_C, \nu_C^2) \\
\text{Restrictive:} \quad & p(h_R) \sim N(\gamma_R \mu_L, \nu_R^2) \\
\text{Moderate:} \quad & p(h_M) \sim N(\gamma_M \mu_L + \delta_f, \nu_M^2) \\
\text{Liberal:} \quad & p(h_L) \sim N(\mu_L + \delta_f, \nu_L^2)
\end{aligned}$$

We set prior values of each standard deviation (ν) equal to 30% of the mean (CV = 0.3) to account for additional variation due to changes in regulations in the other Flyways and their unpredictable effects on the harvest rates of eastern mallards. We then specified the following prior distribution and parameter values for the liberal regulatory alternative:

Closed (in US only):

$p(\mu_C) \sim N\left(0.08, \frac{0.024^2}{6}\right)$

$p(\nu_C^2) \sim Scaled\,Inv - \chi^2(6, 0.024^2)$

Restrictive:

$p(\gamma_R) \sim N\left(0.76, \frac{0.228^2}{6}\right)$

$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.0404^2)$

Moderate:

$p(\gamma_M) \sim N\left(0.92, \frac{0.28^2}{6}\right)$

$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.0488^2)$

Liberal:

$p(\mu_L) \sim N\left(0.1771, \frac{0.0531^2}{6}\right)$

$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.0531^2)$

A previous analysis suggested that the effect of the framework-date extension on eastern mallards would be of lower magnitude and more variable than on mid-continent mallards (U.S. Fish and Wildlife Service 2000). Therefore, we specified the following prior distribution for the marginal effect of the framework-date extension for eastern mallards as:

$$p(\delta_f) \sim N\left(0.01, 0.01^2\right)$$

The prior distributions were multiplied by the likelihood functions based on the last 15 years of data under liberal regulations, and the resulting posterior distributions were evaluated with Markov Chain Monte Carlo simulation. Posterior estimates of model parameters and of annual harvest rates are provided in Table G.2.

Western

We modeled harvest rates of western mallards using a similar parameterization as that used for mid-continent and eastern mallards. However, we did not explicitly model the effect of the framework date extension because

Table G.2 – Parameter estimates for predicting eastern mallard harvest rates resulting from a hierarchical, Bayesian analysis of eastern mallard band-recovery information from 2002 to 2016.

Parameter	Estimate	SD	Parameter	Estimate	SD
μ_C	0.0796	0.0259	h_{2002}	0.1454	0.0124
ν_C	0.0232	0.0058	h_{2003}	0.1103	0.0097
γ_R	0.7596	0.0935	h_{2004}	0.1341	0.0115
ν_R	0.0392	0.0100	h_{2005}	0.1460	0.0123
γ_M	0.9227	0.1148	h_{2006}	0.1266	0.0111
ν_M	0.0473	0.0118	h_{2007}	0.1212	0.0123
μ_L	0.1377	0.0118	h_{2008}	0.1363	0.0107

δ_f	0.0016	0.0092	h_{2010}	0.1310	0.0117
			h_{2011}	0.1113	0.0093
			h_{2012}	0.1314	0.0109
			h_{2013}	0.1511	0.0111
			h_{2014}	0.1467	0.0108
			h_{2015}	0.1272	0.0094
			h_{2016}	0.1306	0.0106

we did not use data observed prior to when framework date extensions were available. In the western mallard parameterization, the effect of the framework date extensions are implicit in the expected mean harvest rate expected under the liberal regulatory option.

$$\text{Closed:} \quad p(h_C) \sim N(\mu_C, \nu_C^2)$$
$$\text{Restrictive:} \quad p(h_R) \sim N(\gamma_R \mu_L, \nu_R^2)$$
$$\text{Moderate:} \quad p(h_M) \sim N(\gamma_M \mu_L, \nu_M^2)$$
$$\text{Liberal:} \quad p(h_L) \sim N(\mu_L, \nu_L^2)$$

We set prior values of each standard deviation (ν) equal to 30% of the mean (CV = 0.3) to account for additional variation due to changes in regulations in the other Flyways and their unpredictable effects on the harvest rates of western mallards. We then specified the following prior distribution and parameter values for the liberal regulatory alternative:

Closed (in US only):

$p(\mu_C) \sim N\left(0.0088, \frac{0.00264^2}{6}\right)$

$p(\nu_C^2) \sim Scaled\,Inv - \chi^2(6, 0.00264^2)$

Restrictive:

$p(\gamma_R) \sim N\left(0.51, \frac{0.153^2}{6}\right)$

$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.01867^2)$

Moderate:

$$p(\gamma_M) \sim N\left(0.85, \frac{0.255^2}{6}\right)$$

$$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0, 0.03112^2)$$

Liberal:

$$p(\mu_L) \sim N\left(0.1220, \frac{0.03661^2}{6}\right)$$

$$p(\nu_R^2) \sim Scaled\,Inv - \chi^2(6, 0.03661^2)$$

The prior distributions were multiplied by the likelihood functions based on the last 9 years of data under liberal regulations, and the resulting posterior distributions were evaluated with Markov Chain Monte Carlo simulation. Posterior estimates of model parameters and of annual harvest rates are provided Table G.3.

Table G.3 – Parameter estimates for predicting western mallard harvest rates resulting from a hierarchical, Bayesian analysis of western mallard band-recovery information from 2008 to 2016.

Appendix H   Northern Pintail Models

The Flyway Councils have long identified the northern pintail as a high-priority species for inclusion in the AHM process. In 2010, the USFWS and Flyway Councils adopted an adaptive management framework to inform northern pintail harvest management. A detailed progress report that describes the evolution of the pintail harvest strategy is available online (http://www.fws.gov/migratorybirds/NewsPublicationsReports.html). The northern pintail adaptive harvest management protocol considers two population models that represent alternative hypotheses about the effect of harvest on population dynamics: one in which harvest is additive to natural mortality, and another in which harvest is compensatory to natural mortality. We describe the technical details of the northern pintail model set below.

Latitude Bias Correction Model

Northern pintails tend to settle on breeding territories farther north during years when the prairies are dry and farther south during wet years. When pintails settle farther north, a smaller proportion are counted during the Waterfowl Breeding Population and Habitat Survey (WBPHS strata: 1–18, 20–50, 75–77), thus the population estimate is biased low in comparison to years when the birds settle farther south. This phenomenon may be a result of decreased detectability of pintails during surveys in northern latitudes compared to southern latitudes or because birds settle in regions not covered by the survey. Runge and Boomer (2005) developed an empirical relationship to correct the observed breeding population estimates for this bias. Based on this approach, the latitude-adjusted breeding population size ($cBPOP_t$) in year t, can be calculated with

$$cBPOP_t = e^{ln(oBPOP_t) + 0.741(mLAT_t - 51.68)}$$

where $oBPOP_t$ is the observed breeding population size in year t and $mLAT_t$ is the mean latitude of the observed breeding population in year t. The mean latitude of the pintail breeding population distribution is based on the geographical centroid of each stratum in the traditional survey area (WBPHS strata: 1–18, 20–50, 75–77). In year t, we calculate a mean latitude ($mLAT_t$) weighted by the population estimates from each strata with

$$mLAT_t = \sum_j [Lat_j(oBPOP_{t,j}/oBPOP_t)]$$

where Lat_j is the latitude of survey stratum j.

Population Models

Two population models are considered: one in which harvest is additive to natural mortality, and another in which harvest is compensatory to natural mortality. The models differ in how they handle the winter survival rate. In the additive model, winter survival rate is a constant, whereas winter survival is density-dependent in the compensatory model.

For the additive harvest mortality model, the latitude-adjusted population size ($cBPOP$) in year $t + 1$, is calculated with

$$cBPOP_{t+1} = \left(cBPOP_t s_s \left(1 + \gamma_R \hat{R}_t\right) - \frac{\hat{H}_t}{(1 - c)} \right) s_w$$

where $cBPOP_t$ is the latitude-adjusted breeding population size in year t, s_s and s_w are the summer and winter survival rates, respectively, γ_R is a bias-correction constant for the age-ratio, c is the crippling loss rate, $\hat{R}_t$ is the predicted age-ratio, and $\hat{H}_t$ is the predicted continental harvest. The model uses the following constants: $s_s = 0.70$, $s_w = 0.93$, $\gamma_R = 0.8$, and $c = 0.20$.

The compensatory harvest mortality model serves as a hypothesis that stands in contrast to the additive harvest mortality model, positing a strong but realistic degree of compensation. The compensatory model assumes that the mechanism for compensation is density-dependent post-harvest (winter) survival (Runge 2007). The form is a logistic relationship between winter survival and post-harvest population size, with the relationship anchored around the historic mean values for each variable. For the compensatory model, predicted winter survival rate in year t (s_t) is calculated as

$$s_t = s_0 + (s_1 - s_0)\left[1 + e^{-(a + b(P_t - \bar{P}))}\right]^{-1},$$

where s_1 (upper asymptote) is 1.0, s_0 (lower asymptote) is 0.7, b (slope term) is -1.0, P_t is the post-harvest population size in year t (expressed in millions), $\bar{P}$ is the mean post-harvest population size (4.295 million from 1974 through 2005), and

$$a = \text{logit}\left(\frac{\bar{s} - s_0}{s_1 - s_0}\right)$$

or

$$a = \log\left(\frac{\bar{s} - s_0}{s_1 - s_0}\right) - \log\left\{1 - \left(\frac{\bar{s} - s_0}{s_1 - s_0}\right)\right\},$$

where $\bar{s}$ is 0.93 (mean winter survival rate).

Age Ratio Submodel

Recruitment $(\hat{R})$ in year t is measured by the vulnerability-adjusted, female age-ratio in the fall population and is predicted as

$$\hat{R}_t = e^{(7.6048 - 0.13183mLAT_t - 0.09212cBPOP_t)}$$

where $mLAT_t$ is the mean latitude of the observed breeding population in year t and $cBPOP_t$ is the latitude-adjusted breeding population in year t (expressed in millions).

Harvest Submodel

Predicted continental harvest $(\hat{H})$ in year t is calculated with

$$\hat{H}_t = H_{PF} + H_{CF} + H_{MF} + H_{AF} + H_{AKCan}$$

where H_{PF}, H_{CF}, H_{MF}, and H_{AF} are the predicted harvest in the Pacific, Central, Mississippi, and Atlantic Flyways, respectively. The expected harvest from Alaska and Canada H_{AKCan} is assumed fixed and equal to 67,000 birds. Flyway specific harvest predictions are calculated with

Table H.1 – Total pintail harvest expected from the set of regulatory alternatives specified for each Flyway under the northern pintail adaptive harvest management protocol.

Pacific Atlantic	Central Mississippi	Total Harvest
Closed	Closed	67,000
Liberal 1	Closed	278,000
Liberal 1	Restrictive 3	410,000
Liberal 1	Moderate 3	523,000
Liberal 1	Liberal 1	569,000
Liberal 2	Closed	357,000
Liberal 2	Restrictive 3	490,000
Liberal 2	Moderate 3	603,000
Liberal 2	Liberal 2	672,000

$$H_{PF} = -12051.41 + 1160.960 days + 73911.49 bag$$

$$H_{CF} = -95245.20 + 2946.285 days + 15228.03 bag + 23136.04 sis$$

$$H_{MF} = -59083.66 + 3413.49 days + 7911.95 bag + 59510.10 sis$$

$$H_{PF} = -2403.06 + 360.950 days + 5494.00 bag$$

where $days$ is the season length, bag is the daily bag limit, and sis is an indicator variable with value equal to 0 (full season equal to length from general duck season) or 1 (restrictive season within the liberal or moderate regulatory alternative for general duck season, i.e., partial season). Each regulatory combination of bag limit and season length has an associated predicted pintail harvest (Table H.1).

Model Weights

The relative degree of confidence that we have in the additive or compensatory mortality hypothesis can be represented with model weights that are updated annually from a comparison of model specific predictions and observed population sizes. For the period 1974–2016, the subsequent year's breeding population size (on the latitude-adjusted scale) was predicted with both the additive and compensatory models, and compared to the observed breeding population size (on the latitude-adjusted scale). The mean-squared error of the predictions from the additive model (MSE_{add}) was calculated as:

$$MSE_{add} = \frac{1}{(t - 1975) + 1} \sum_{t=1975}^{t} \left(cBPOP_t - cBPOP_t^{add} \right)^2,$$

and the mean-squared error of the predictions from the compensatory model were calculated in a similar manner.

We calculated model weights for the additive and compensatory model as a function of their relative mean-squared errors. The model weight for the additive model (W_{add}) was determined by

$$W_{add} = \cfrac{\cfrac{1}{MSE_{add}}}{\cfrac{1}{MSE_{add}} + \cfrac{1}{MSE_{comp}}}$$

The model weight for the compensatory model was found in a corresponding manner, or by subtracting the additive model weight from 1.0. As of 2017, the compensatory model did not fit the historic data as well as the additive model; the model weights were 0.573 for the additive model and 0.427 for the compensatory model.

Equilibrium Conditions

Equilibrium analyses of the additive model suggest a carrying capacity of 7.32 million (on the latitude-adjusted scale), maximum sustained yield (MSY) of 444,000 at an equilibrium population size of 3.34 million, and harvest rate of 10.7% (Runge and Boomer 2005). The yield curve resulting from the compensatory model is significantly skewed compared to the additive model (Figure H.1). Compared to the additive model, the compensatory model results in a lower carrying capacity (4.67 million), a higher MSY (560 thousand) at a lower equilibrium population size (3.00 million), and a higher maximum harvest rate (14.8%).

The average model, based on 2017 model weights, produces a yield curve that is intermediate between the additive and compensatory models. An equilibrium analysis of the weighted model results in carrying capacity, MSY, equilibrium population size at MSY, and maximum harvest rate that are intermediate between the additive and compensatory model results (5.45 million, 492 thousand, 3.11 million, and 12.6% respectively).
Figure H.1 – Harvest yield curves resulting from an equilibrium analysis of the northern pintail model set based on 2017 model weights.

Appendix I   Scaup Model

We use a state-space formulation of scaup population and harvest dynamics within a Bayesian estimation framework (Meyer and Millar 1999, Millar and Meyer 2000). This analytical framework allows us to represent uncertainty associated with the monitoring programs (observation error) and the ability of our model formulation to predict actual changes in the system (process error).

Process Model

Given a logistic growth population model that includes harvest (Schaefer 1954), scaup population and harvest dynamics are calculated as a function of the intrinsic rate of increase (r), carrying capacity (K), and harvest (H_t). Following Meyer and Millar (1999), we scaled population sizes by K (i.e., $P_t = N_t/K$) and assumed that process errors (ϵ_t) are lognormally distributed with a mean of 0 and variance $\sigma^2_{process}$. The state dynamics can be expressed as

$$P_{1974} = P_0 e^{\varepsilon_{1974}}$$

$$P_t = (P_{t-1} + rP_{t-1}(1 - P_{t-1}) - H_{t-1}/K)\, e^{\varepsilon_t}, \quad t = 1975, \ldots, 2016,$$

where P_0 is the initial ratio of population size to carrying capacity. To predict total scaup harvest levels, we modeled scaup harvest rates (h_t) as a function of the pooled direct recovery rate (f_t) observed each year with

$$h_t = f_t/\lambda_t.$$

We specified reporting rate (λ_t) distributions based on estimates for mallards (*Anas platyrhynchos*) from large scale historical and existing reward banding studies (Henny and Burnham 1976, Nichols et al. 1995*b*, P. Garrettson unpublished data). We accounted for increases in reporting rate believed to be associated with changes in band type (e.g., from AVISE and new address bands to 1-800 toll free bands) by specifying year specific reporting rates according to

$$\lambda_t \sim Normal(0.38, 0.04), \quad t = 1974, \ldots, 1996$$
$$\lambda_t \sim Normal(0.70, 0.04), \quad t = 1997, \ldots, 2016.$$

We then predicted total scaup harvest (H_t) with

$$H_t = h_t\left[P_t + rP_t(1 - P_t)\right]K, \quad t = 1974, \ldots, 2016.$$

Observation Model

We compared our predictions of population and harvest numbers from our process model to the observations collected by the Waterfowl and Breeding Habitat Survey (WBPHS) and the Harvest Survey programs with the following relationships, assuming that the population and harvest observation errors were additive and normally distributed. May breeding population estimates were related to model predictions by

$$N_t^{Observed} - P_t K = \varepsilon_t^{BPOP},$$

where

$$\varepsilon_t^{BPOP} \sim N(0, \sigma_{t,BPOP}^2), \quad t = 1974, \dots, 2016,$$

where $\sigma_{t,BPOP}^2$ is specified each year with the BPOP variance estimates from the WBPHS.

We adjusted our harvest predictions to the observed harvest data estimates with a scaling parameter (q) according to

$$H_t^{Observed} - (h_t [P_t + rP_t (1 - P_t)] K) / q = \varepsilon_t^H, \quad t = 1974, \dots, 2016,$$

where,

$$\varepsilon_t^H \sim N(0, \sigma_{t,Harvest}^2).$$

We assumed that appropriate measures of the harvest observation error $\sigma_{t,Harvest}^2$ could be approximated by assuming a coefficient of variation for each annual harvest estimate equal to 0.15 (Paul Padding pers. comm.). The final component of the likelihood included the year specific direct recovery rates that were represented by the rate parameter (f_t) of a Binomial distribution indexed by the total number of birds banded preseason and estimated with,

$$f_t = m_t / M_t,$$
$$m_t \sim Binomial(M_t, f_t)$$

where m_t is the total number of scaup banded preseason in year t and recovered during the hunting season in year t and M_t is the total number of scaup banded preseason in year t.

Bayesian Analysis

Following Meyer and Millar (1999), we developed a fully conditional joint probability model, by first proposing prior distributions for all model parameters and unobserved system states and secondly by developing a fully conditional likelihood for each sampling distribution.

Prior Distributions

For this analysis, a joint prior distribution is required because the unknown system states P are assumed to be conditionally independent (Meyer and Millar 1999). This leads to the following joint prior distribution for the model parameters and unobserved system states

$$P(r, K, q, f_t, \lambda_t, \sigma_{Process}^2, P_0, P_{1,\dots,T}) =$$
$$p(r)p(K)p(q)p(f_t)p(\lambda_t)p(\sigma_{Process}^2)p(P_0)p(P_1|P_0, \sigma_{Process}^2)$$
$$\times \prod_{t=2}^{n} p(P_t|P_{t-1}, r, K, f_{t-1}, \lambda_{t-1}, \sigma_{Process}^2)$$

In general, we chose non-informative priors to represent the uncertainty we have in specifying the value of the parameters used in our assessment. However, we were required to use existing information to specify

informative priors for the initial ratio of population size to carrying capacity (P_0) as well as the reporting rate values (λ_t) specified above that were used to adjust the direct recovery rate estimates to harvest rates.

We specified that the value of P_0, ranged from the population size at maximum sustained yield ($P_0 = N_{MSY}/K = (K/2)/K = 0.5$) to the carrying capacity ($P_0 = N/K = 1$), using a uniform distribution on the log scale to represent this range of values. We assumed that the exploitation experienced at this population state was somewhere on the right-hand shoulder of a sustained yield curve (i.e., between MSY and K). Given that we have very little evidence to suggest that historical scaup harvest levels were limiting scaup population growth, this seems like a reasonable prior distribution.

We used non-informative prior distributions to represent the variance and scaling terms, while the priors for the population parameters r and K were chosen to be vague but within biological bounds. These distributions were specified according to

$$
\begin{aligned}
P_0 &\sim Uniform(ln(0.5), 0), \\
K &\sim Lognormal(2.17, 0.667), \\
r &\sim Uniform(0.00001, 2), \\
f_t &\sim Beta(0.5, 0.5), \\
q &\sim Uniform(0.0, 2), \\
\sigma^2_{Process} &\sim Inverse\ Gamma(0.001, 0.001).
\end{aligned}
$$

Likelihood

We related the observed population, total harvest estimates, and observed direct recoveries to the model parameters and unobserved system states with the following likelihood function:

$$
\begin{aligned}
P(N_{1,...,T}, H_{1,...,T}, m_{1,...,T} M_{1,...,T} | r, K, f_t, \lambda_t, q, \sigma^2_{Process}, \sigma^2_{Harvest}, P_{1,...,T}) = \\
\times \prod_{t=1}^{T} p(N_t | P_t, K, \sigma^2_{BPOP}) \times \prod_{t=1}^{T} p(H_t | P_t, r, K, q, f_t, \lambda_t, \sigma^2_{Harvest}) \\
\times \prod_{t=1}^{T} p(m_t | M_t, f_t)
\end{aligned}
$$

Posterior Evaluation

Using Bayes theorem we then specified a posterior distribution for the fully conditional joint probability distribution of the parameters given the observed information according to

$$
\begin{aligned}
P(r, K, q, f_t, \lambda_t, \sigma^2_{Process}, P_0, P_{1,...,T} | N_{1,...,T}, H_{1,...,T}, m_{1,...,T}, M_{1,...,T}) \propto \\
p(r)p(K)p(q)p(f_t)p(\lambda_t)p(\sigma^2_{Process})p(P_0)p(P_1 | P_0, \sigma^2_{Process}) \\
\times \prod_{t=2}^{n} p(P_t | P_{t-1}, r, K, f_{t-1}, \lambda_{t-1}, \sigma^2_{Process}) \times \prod_{t=1}^{T} p(N_t | P_t, K, \sigma^2_{BPOP}) \\
\times \prod_{t=1}^{T} p(H_t | P_t, r, K, q, f_t, \lambda_t, \sigma^2_{Harvest}) \times \prod_{t=1}^{T} p(m_t | M_t, f_t)
\end{aligned}
$$

Table I.1 – Model parameter estimates resulting from a Bayesian analysis of scaup breeding population, harvest, and banding information from 1974 to 2016.

Parameter	Mean	SD	2.5% CI	Median	97.5% CI
r	0.1530	0.0540	0.0723	0.1446	0.2803
K	8.4215	1.6513	6.0630	8.0865	12.1500
σ^2	0.0074	0.0031	0.0030	0.0069	0.0149
q	0.6855	0.0394	0.6105	0.6841	0.7672

We used MCMC methods to evaluate the posterior distribution using WinBUGS (Spiegelhalter et al. 2003). We randomly generated initial values and simulated 5 independent chains each with 1,000,000 iterations. We discarded the first half of the simulation and thinned each chain by 250, yielding a sample of 10,000 points. We calculated Gelman-Rubin statistics (Brooks and Gelman 1998) to monitor for lack of convergence. The state-space formulation and Bayesian analysis framework provided reasonable fits to the observed breeding population and total harvest estimates with realistic measures of variation. The 2017 posterior estimates of model parameters based on data from 1974 to 2016 are provided in Table I.1.

We further summarized the simulation results for r, K, and the scaling parameter q to admit parametric uncertainty with a formal correlation structure within the optimization procedure used to calculate the harvest strategy. We first defined a joint distribution for 3 discrete outcomes for each of the 3 population parameters. We used the 30 and 70 percent quantiles for each parameter as the cut points to define three bins for which to discretize 3 values of each posterior distribution. We then determined the frequency of occurrence of each of the 27 possible combinations of each parameter value falling within the 3 bins from the MCMC simulation results. These frequencies were then assigned parameter values based on the midpoint of the bin ranges (15, 50, 85 percent quantiles) to specify the joint distribution of the population parameter values used in the optimization.
